Course Wavelets and Applications – Outline

1. Introduction: from Fourier to Wavelets
2. The 1D Continuous Wavelet Transform
3. Wavelet zoom: a local characterization of functions
4. Lab1: 1D Continuous Wavelet Transform
5. The 2D Continuous Wavelet Transform
6. Wavelet Bases (Haar, multiresolution, orthogonal wavelet bases)
7. Fast Wavelet Transform (the 1D and 2D cases)
8. Lab 2: Fast Wavelet Transform, image compression and denoising
9. Approximation in wavelet bases (sparsity, compression, denoising)
10. Application 1: The dual-tree complex wavelet transform and the scattering transform for deep learning
11. Application 2: Introduction to wavelets on graphs
12. Lab 3: Dedicated to the project
Course evaluation

1. **2 lab sessions using the library PyWavelet** (results to be sent by email)

2. **Examination. 1 project** consisting on:
   - Choosing a research article using wavelets for a given application.
   - Reading and understanding the article, **writing a summary of what you expect to implement** (**due to December 9th**).
   - Practical work: implementation of the method presented in the article (Matlab or Python).
   - Writing a report including figures of results.

3. **Ensimag students must form pairs** for lab sessions and the project (precise both your names on the summary)

---

Notes:

- Wavelets are essential tools in the analysis of complex data, providing a powerful method for representing and interpreting data in a variety of fields.

- In numerical simulation, wavelets are used to model and simulate turbulent flows, which are challenging to predict due to their chaotic behavior.

- Divergence-free wavelets are particularly useful in simulations involving fluid dynamics, where the conservation of mass is a fundamental principle.
A success story

**WSQ (1993)** is the FBI's Wavelet Scalar Quantization: it is a national standard for the collecting, encoding, storing, and retrieving digitized fingerprint images.

**JPEG 2000** is an image coding system that uses state-of-the-art compression techniques based on wavelet technology.

**Academy Sci-Tech Award 2013**
Awarded to **Theodore Kim, Nils Thuerey, Dr. Markus Gross and Doug James** for the invention, publication and dissemination of “Wavelet Turbulence” software.

Gravitational waves detection

Analytic wave form derived from Einstein’s equations (Thibault Damour et al.)

$$s(t) = c|t - t_0|^{-\frac{1}{4}} \cos(\omega|t - t_0|^\frac{5}{8} + \phi)$$

with $c$, $\omega$, $\phi$ and $t_0$ are constants ($t_0 =$ time when the stars are merging)

Credits: B.P. Abbott et al., Observation of Gravitational Waves from a Binary Black Hole Merger
Gravitational waves detection

Credits: B.P. Abbott et al., Observation of Gravitational Waves from a Binary Black Hole Merger
Gravitational waves detection

- Gravitational waves are perturbation of the space-time metric, predicted by Einstein and steadily sent to the Earth.

- Gravitational waves, produced during the final fraction of second of the merger of two black holes into a single, are chirps like a modulated song of a bird, which are very tenious (noise/signal > $10^3$).

- Pattern detected by the 2 arms of an interferometer, separated by 3000km and 4km long, use laser lights and distant mirrors to be sensitive to deformations smaller than $10^{-19}$ m (!).

- Detecting a short-lived chirp buried inside a very noisy signal cannot be extracted by Fourier analysis (adapted to stationary signals).

- Wavelet analysis extends and overcomes Fourier limitation by exploring the time-frequency / time-scale structure of the data. It explores what is beyond our senses by yielding details that cannot be perceived by our eyes (it acts like a "zoom").

Gravitational waves detection

Klimenko’s algorithm: Coherent Wave Burst

- Projection on bases of functions reasonably localized in time and frequency: Wilson transforms (modification of Gabor transforms)
- The window can be Meyer scaling function. The signal processing is performed on 7 Wilson bases (and their quadrature bases) each obtained by a dilation of factor 2 of the window
- Several decompositions at different time scales. Inspiral requires good frequency resolution, merger requires good time resolution: compromise between time frequency and time scale analysis
- Retain time-frequency pixels that are “phase coherent”. Can detect unexpected sources. Fast and robust algorithm.

Credits: Eric Chassande-Mottin
Gravitational waves detection

Klimenko’s algorithm: Coherent Wave Burst

Search for rare transients with low signal to noise ratio. Two ways:

- **Matched filtering.** Expected signal is known, targeted search signature of binary black-hole merger as predicted by general relativity

- **Time-frequency excess power.** Expected signal is unknown, search transients appearing in phase in all detectors with no waveform prior (general relativity not needed)

Wavelet analysis explores beyond our senses

Credits: S. Klimenko et al., arXiv:1511.05999 + The economist
A new window on the universe

“It’s like Galileo pointing the telescope for the first time at the sky. You’re opening your eyes — in this case, our ears — to a new set of signals from the universe that our previous technologies did not allow us to receive, study and learn from.”

Vassiliki Kalogera

“Up until now, we’ve been deaf to gravitational waves. What’s going to come now is we’re going to hear more things, and no doubt we’ll hear things that we expected to hear... but we will also hear things that we never expected.”

David Reitze

“Writing the score while listening to the music, then analyzing and interpreting the score, is, in a sense, what Klimenko does to detect gravitational waves.”

Yves Meyer

Back to the time of Ptolemy...
Who Wants to Be a Millionaire?
A pre-Copernican TV show

Credits: "Qui veut gagner des millions" (http://www.youtube.com/watch?v=ekmtqODjrSI)
You are now aware that the "universe" is the name given by most astronomers to the sphere, the centre of which is the centre of the earth, while its radius is equal to the straight line between the centre of the sun and the centre of the earth. This is the common account as you have heard from astronomers. But Aristarchus has brought out a book consisting of certain hypotheses, wherein it appears, as a consequence of the assumptions made, that the universe is many times greater than the "universe" just mentioned. His hypotheses are that the fixed stars and the sun remain unmoved, that the earth revolves about the sun on the circumference of a circle, the sun lying in the middle of the orbit, and that the sphere of the fixed stars, situated about the same centre as the sun, is so great that the circle in which he supposes the earth to revolve bears such a proportion to the distance of the fixed stars as the centre of the sphere bears to its surface.

Mars apparent retrograde motion

Credits: Tunc Tezel & Robert Rynasiewicz
If anyone were to believe that the sun truly moves in the space of a year through the zodiac, which Ptolemy and Tycho Brahe believed, then it is necessary to concede that the paths of the three superior Planets through ethereal space, composed as they are of several motions, are in reality spirals in the figure of a pretzel, in the general fashion that follows.

Johannes Kepler
Mars apparent retrograde motion

Spirograph

Epicycles

Credits: El Jj (http://www.youtube.com/watch?v=uazPP0ny3XQ)
Roots of epicycles: from Hipparque to Kepler

- **Hipparque**’s epicycles theory based on *Apollonius of Perga*’s works (at the end of the 3rd century BC) + **Seleucus of Seleucia**
- **Ptolemy** refined the deferent-and-epicycle concept and introduced the equant as a mechanism for accounting for velocity variations in the motions of the planets
- **Copernicus** and his contemporaries were therefore using **Ptolemy**’s methods and finding them trustworthy well over a thousand years after **Ptolemy**’s original work was published
- In keeping with past practice, **Copernicus** used the deferent/epicycle model in his theory but his epicycles were small and were called *epicyclets*
- **Copernicus** eliminated **Ptolemy**’s somewhat-maligned equant but at a cost of additional epicycles. Various 16th-century books based on **Ptolemy** and **Copernicus** use about equal numbers of epicycles

The Paradigm shift: Kepler, Galileo and Newton discoveries

Newton standing on the shoulders of giants

- The intellectual climate of the time "remained dominated by Aristotelian philosophy and the Ptolemaic astronomy. At that time there was no reason to accept the Copernican theory, except for its mathematical simplicity." Tycho Brahe’s system ("that the earth is stationary, the sun revolves about the earth, and the other planets revolve about the sun") also directly competed with Copernicus.

The Paradigm shift: Kepler, Galileo and Newton discoveries
Newton standing on the shoulders of giants

- **Johannes Kepler** developed his laws of planetary motion using measurements made at Tycho’s observatory. In Astronomia nova (1609), **Kepler** made a diagram of the movement of Mars in relation to Earth if Earth were at the center of its orbit, which shows that Mars’orbit would be completely imperfect and never follow along the same path. To solve the apparent derivation of Mars’orbit from a perfect circle, **Kepler** derived both a mathematical definition and, independently, a matching **ellipse** around the Sun to explain the motion of the red planet. Kepler’s laws were born.

Credits: Wayne Pafko (http://www.pafko.com/tycho/observe.html)
Galileo was able to look at the night sky with the newly invented telescope. He published his discoveries that Jupiter is orbited by moons and that the Sun rotates in his Sidereus Nuncius (1610) and Letters on Sunspots (1613), respectively. Around this time, he also announced that Venus exhibits a full range of phases (satisfying an argument that had been made against Copernicus). Finally he discovered that the moon presents mountains, valleys and craters which depreciates the Aristotelian conception.
The Paradigm shift: Kepler and Galileo discoveries
Newton standing on the shoulders of giants

- **Galileo** was able to look at the night sky with the newly invented telescope. He published his discoveries that Jupiter is orbited by moons and that the Sun rotates in his Sidereus Nuncius (1610)[93] and Letters on Sunspots (1613), respectively. Around this time, he also announced that Venus exhibits a full range of phases (satisfying an argument that had been made against Copernicus). Finally he discovered that the moon presents mountains, valleys and craters which depreciates the Aristotelian conception.

- **Galileo** formulated the principle of inertia which helped to explain why everything would not fall off the earth if it were in motion.

- **Isaac Newton** formulated the universal law of gravitation and the laws of mechanics in his 1687 Principia, which unified terrestrial and celestial mechanics, was the heliocentric view generally accepted.

Why was Ptolemy’s system so efficient?

... or more exactly thanks to him: Joseph Fourier

Just like Mr Jourdain speaking prose, astronomers made Fourier series without realizing it

Credits: 3blue1brown (http://www.youtube.com/watch?v=-qgreAUpPwM)
Fourier series: an intuition behind the decomposition

Periodic signals can be decomposed onto the Fourier basis

\[ f(t) = \cdots + c_{-4}e^{-2\cdot2\pi it} + c_{-1}e^{-1\cdot2\pi it} + c_0e^{0\cdot2\pi it} + c_1e^{1\cdot2\pi it} + c_2e^{2\cdot2\pi it} + \cdots \]

Fourier series analysis

The **Fourier analysis** decomposes a signal (function) \( f(x) \) \((x = \text{times})\) into a sum of sinusoidal functions:

- For a \( T \)-periodic function \( f \), with \( f \in L^2(0, T) \):

  \[
  f(x) = \sum_{n \in \mathbb{Z}} c_n(f) e^{2i\pi \frac{n}{T} x} \quad \text{(synthesis)}
  \]

where the Fourier coefficients are:

\[
  c_n(f) = \frac{1}{T} \int_0^T f(x) e^{-2i\pi \frac{n}{T} x} \, dx \quad \text{(analysis)}
\]

are related to the frequency \( \frac{n}{T} \) (in Hz).

**Parseval equality:**

\[
  \sum_{n \in \mathbb{Z}} |c_n(f)|^2 = \frac{1}{T} \int_0^T |f(x)|^2 \, dx \quad \text{(energy conservation)}
\]
Fourier series limitations

Discontinuities require a lot of sinusoids to be described

\[ f(x) = \begin{cases} 
-1 & \text{if } -\pi \leq x < 0 \\
+1 & \text{if } 0 \leq x < \pi 
\end{cases} = \sum_{n=1}^{+\infty} \frac{4}{\pi(2n-1)} \sin((2n-1)x) \]

Fourier transform

- For a function $f \in L^2(\mathbb{R})$:

$$f(x) = \int_{-\infty}^{+\infty} \hat{f}(\nu) e^{2i\pi \nu x} \, d\nu \quad \text{(synthesis)}$$

where the Fourier transform of $f$ is:

$$\hat{f}(\nu) = \int_{-\infty}^{+\infty} f(x) e^{-2i\pi \nu x} \, dx \quad \text{(analysis)}$$

gives information on $f$ for the frequency $\nu$.

Plancherel-Parseval equality:

$$\int_{-\infty}^{+\infty} |\hat{f}(\nu)|^2 \, d\nu = \int_{-\infty}^{+\infty} |f(x)|^2 \, dx \quad \text{(energy conservation)}$$
Fourier transform: an intuition behind the transformation
aperiodic signals can also be decomposed onto the continuous dictionary of exponentials

\[ \hat{g}(f) = \int_{t_1}^{t_2} g(t) e^{-2\pi i f t} dt \]

Credits: 3blue1brown (https://www.youtube.com/watch?v=spUNpyF58BY)
Fourier Transform visualization

Wrap the signal around a circle

$\hat{g}(f) = \frac{1}{N} \sum_{k=1}^{N} g(t_k) e^{-2\pi if t_k}$

To find the energy at a particular frequency, the signal is wrapped around a circle at the particular frequency and the points along the path are averaged.

Credits: Elan Ness-Cohn
Fourier transform limitations

Example: two musical notes played at the same time

Figure: Signal $f(x) = \sin(40\pi x) + \sin(170\pi x)$ (top), and modulus of its Fourier Transform $\hat{f}(\nu)$ (bottom)
Fourier transform limitations

Example of two musical notes played one after the other

The frequency analysis do not inform on the transient phenomenon in the signal ⇒ Loss of temporal localization
Fourier cat transformation

Hi, Dr. Elizabeth?
Yeah, uh... I accidentally took the Fourier transform of my cat...

Meow!
Take home message

To sum up

- Periodic functions (as planets motion along closed orbit) can be approximated by epicycles, that is by Fourier series.
- Fitting data do not necessarily mean that the mechanics behind is understood, and saving the phenomena can lead to a kind of overfitting. What is a good model or a good theory?
- The relativity of motion makes possible to consider different coordinate systems to describe trajectories. Something which is well known by physicists: the choice of the frame of reference can greatly simplify mathematical calculations.
- An appropriate representation of the signal can also reduced the number of parameters needed to encode its information.

⇒ Toward a sparse representation of signals
Take home message

To sum up

- Fourier series decomposition allowed Joseph Fourier to solve partial differential equations (heat equation).
- Extension to the Fourier transform for aperiodic signal also reveals the frequency contents of the signal, but suffer of the same issues:
  - Discontinuities involve a lot of significant coefficients in the decomposition, whose the decrease in amplitudes encodes the global regularity of the signal.
  - Losing the temporal localization, the Fourier transform does not allow to capture transient phenomena in the signal.

⇒ Toward a time-frequency representation of signals
The Continuous Wavelet Transform
Short Time Fourier Transform (STFT)

Multiplication of the signal $f(x)$ by a window $w(x - b)$ (real and of size $a_0$) and computation of the Fourier transform of this product:

$$Sf(\nu, b) = \int_{-\infty}^{+\infty} f(x)w(x - b)e^{-2i\pi\nu x} \, dx$$

where $b$ represents time and $\nu$ frequency. $f$ can be recovered from its STFT coefficients:

$$f(x) = C_h \int_{\mathbb{R}^2} Sf(\nu, b)w(x - b)e^{2i\pi\nu x} \, d\nu \, db$$
Special case: the Gabor Transform

- In the Short Time Fourier Transform
  \[ S_f(\nu, b) = \int_{-\infty}^{+\infty} f(x)w(x - b)e^{-2i\pi\nu x} \, dx = \langle f, \psi_{\nu,b} \rangle \]
  the analyzing functions are:
  \[ \psi_{\nu,b} = w(x - b)e^{2i\pi\nu x} \]

- In the **Gabor transform** (1946) the window \( w \) is a Gaussian of scale \( \sigma \):
  \[ w(x) = \frac{1}{\sigma}e^{-\pi\left(\frac{x}{\sigma}\right)^2} \]
  and the Gabor functions are then (\( \sigma = 1 \)):
  \[ g_{\nu,b} = e^{-\pi(x-b)^2}e^{2i\pi\nu x} \]

Kévin Polisano
Wavelets and Applications
Short Time Fourier Transform

Example of two musical notes

The **time-frequency analysis** allows to recover both frequencies (the notes) and temporal information (the temporal order) of the signal $f_1$:

**Figure**: Time-frequency plane with $b$ on the x-axis and $\nu$ on the y-axis, representing the density energy $|Sf(\nu, b)|^2 = |\langle f, g_{\nu,b} \rangle|^2$ called the spectrogram.
Short Time Fourier Transform
Analogy with music scores: an example with a piano

Heisenberg boxes
Time-frequency localization and spread

\[ g_{\xi,b}(t) = w(t - b)e^{i\xi t} \quad \longleftrightarrow \quad \hat{g}_{\xi,b}(\omega) = \hat{w}(\omega - \xi)e^{-ib(\omega - \xi)} \]

\[ \sigma^2_t = \int_{-\infty}^{\infty} (t - b)^2|g_{\xi,b}(t)|^2 dt = \int_{-\infty}^{\infty} t^2|w(t)|^2 dt \]

\[ \sigma^2_\omega = \frac{1}{2\pi} \int_{-\infty}^{\infty} (\omega - \xi)^2|\hat{g}_{\xi,b}(\omega)|^2 d\omega = \frac{1}{2\pi} \int_{-\infty}^{\infty} \omega^2|\hat{w}(t)|^2 d\omega \]
Heisenberg boxes

Example: Gabor limits

\[ g_{s,f}(t) = w(t - s)e^{j2\pi ft} \]

\[ w(t) = (\pi \sigma^2)^{-1/4}e^{-t^2/2\sigma^2} \]

Credits: Pierre Chainais, "De la transformée de Fourier à l’analyse temps-fréquence bivariée"
Heisenberg boxes
Time-frequency localization and spread

- Can we construct a function $f$, with an energy that is highly localized in time and with a Fourier transform $\hat{f}$ having an energy concentrated in a small-frequency interval?

- To reduce the time spread of $f$, we can scale it by $a < 1$, while keeping its total energy constant:

$$f_a(t) = \frac{1}{\sqrt{a}} f \left( \frac{t}{a} \right), \quad \| f_a \|^2 = \| f \|^2$$

- The corresponding Fourier transform is dilated by a factor $1/a$:

$$\hat{f}_a(\omega) = \sqrt{a} \hat{f}(a\omega)$$

$\Rightarrow$ So we lose in frequency localization what we gained in time.
Underlying is a trade-off between time and frequency localization.

Credits: S. Mallat (Wavelet tour)
Heisenberg’s indeterminacy relations

Defining the average location and frequency respectively by:

\[ b = \frac{1}{\|f\|^2} \int_{-\infty}^{\infty} t |f(t)|^2 dt, \quad \xi = \frac{1}{2\pi \|f\|^2} \int_{-\infty}^{\infty} \omega |\hat{f}(\omega)|^2 d\omega \]

The variances around these average values are respectively:

\[ \sigma_t^2 = \frac{1}{\|f\|^2} \int_{-\infty}^{\infty} (t - b)^2 |f(t)|^2 dt, \quad \sigma_\omega^2 = \frac{1}{2\pi \|f\|^2} \int_{-\infty}^{\infty} (\omega - \xi)^2 |\hat{f}(\omega)|^2 d\omega \]

Theorem (Heisenberg’s indeterminacy relations)

The temporal variance and the frequency variance of \( f \in L^2(\mathbb{R}) \) satisfy

\[ \sigma_t \sigma_\omega \geq \frac{1}{2} \]

This inequality is an equality iff \( \exists (b, \xi, c_1, c_2) \in \mathbb{R}^2 \times \mathbb{C}^2 \) such that

\[ f(t) = c_1 e^{i\xi t - c_2 (t-b)^2} \]

Credits: S. Mallat
Heisenberg’s indeterminacy relations

Proof (Weyl): this proof supposes that \( \lim_{|t| \to +\infty} \sqrt{tf(t)} = 0 \) \((*)\) but the theorem is valid for any \( f \in L^2(\mathbb{R}) \). The average time and frequency location of \( e^{-i\xi t}f(t+b) \) is zero. Thus, it is sufficient to prove the theorem for \( b = \xi = 0 \).

Since \( \hat{f}'(t)(\omega) = i\omega \hat{f}(\omega) \), the Plancherel identity applied to \( i\omega \hat{f}(\omega) \) yields

\[
\sigma_t^2 \sigma_\omega^2 = \frac{1}{\|f\|^4} \left( \int_{-\infty}^\infty |t f(t)|^2 dt \right) \left( \int_{-\infty}^\infty |f'(t)|^2 dt \right) (**)
\]

Schwarz’s inequality and the assumption \((*)\) [for the last equality] imply

\[
\sigma_t^2 \sigma_\omega^2 \geq \frac{1}{\|f\|^4} \left( \int_{-\infty}^\infty |t f'(t) f^*(t)| dt \right)^2 \quad \forall z \in \mathbb{C}, \ |z| \geq \text{Re}(z) = \frac{z + z^*}{2}
\]

\[
\geq \frac{1}{\|f\|^4} \left( \int_{-\infty}^\infty \frac{t}{2} (f'(t) f^*(t) + f'^*(t) f(t)) dt \right)^2
\]

\[
\geq \frac{1}{4\|f\|^4} \left( \int_{-\infty}^\infty t (|f(t)|^2)' dt \right)^2 \text{ IBPF} = \frac{1}{4\|f\|^4} \left( \int_{-\infty}^\infty |f(t)|^2 dt \right)^2 = \frac{1}{4}
\]

Credits: S. Mallat (Wavelet tour) (IBPF = Integration By Parts Formula)
Heisenberg’s indeterminacy relations

**Proof:** To obtain an equality, Schwarz’s inesquality applied to (**) must be an equality. This implies that there exists $c_2 \in \mathbb{C}$ such that

$$f'(t) = -2c_1 tf(t)$$

Thus, there exists $c_1 \in \mathbb{C}$ such that

$$f(t) = c_1 e^{-c_2 t^2}$$

When $b \neq 0$ and $\xi \neq 0$ a time and frequency translation yield the result.

**Remark:** motivated by quantum mechanics, Gabor proposed time-frequency atoms that have a minimal spread in a time-frequency plane. By showing that signal decompositions over the dictionary of Gabor atoms are closely related to our perception of sounds, and that they exhibit important structures in speech and music recordings, he demonstrated the importance of localized time-frequency signal processing.

Heisenberg’s indeterminacy relations

Some intuitions behind

**Figure:** Improved frequency measurement over longer time intervals. The uncertainty in the frequency $\Delta f$ decreases as the measurement interval $\Delta t$ increases, and vice versa.

**Credits:** Bruce MacLennan (Gabor Representation)
Heisenberg’s indeterminacy relations
Some intuitions behind

Figure: Measuring frequency by counting maxima in a given time interval. The circled numbers indicate the maxima counted during the measurement interval $\Delta t$. Since signals of other frequencies could also have the same number of maxima in that interval, there is an uncertainty $\Delta f$ in the frequency.

Credits: Bruce MacLennan (Gabor Representation)
Heisenberg’s indeterminacy relations

Some intuitions behind

Figure: Minimum time interval $\Delta t$ to detect frequency difference $\Delta f$. If two signals differ in frequency by $\Delta f$, then a measurement of duration $\Delta t \geq 1/\Delta f$ is required to guarantee a difference in counts of maxima. (Italic numbers indicate maxima of signal of frequency $f$, roman numbers indicate maxima of signal of higher frequency $f + \Delta f$)

\[(f + \Delta f)\Delta t - f \Delta t \geq 1 \iff \Delta f \Delta t \geq 1\]

Short Time Fourier Transform

Examples

1. A sinusoidal wave $f(t) = e^{i\xi_0 t}$ whose Fourier transform is a Dirac $\hat{f}(\omega) = 2\pi \delta(\omega - \xi_0)$ has a STFT:

$$Sf(\xi, b) = \hat{w}(\xi - \xi_0)e^{-ib(\xi - \xi_0)}$$

Its energy is spread over the frequency interval

$$\xi \in [\xi_0 - \sigma_\omega / 2, \xi_0 + \sigma_\omega / 2]$$

2. A Dirac $f(t) = \delta(t - b_0)$ has a STFT:

$$Sf(\xi, b) = w(b - b_0)e^{-i\xi b_0}$$

Its energy is spread in the time interval

$$b \in [b_0 - \sigma_t / 2, b_0 + \sigma_t / 2]$$
Limitation of the Short Time Fourier Transform

The STFT cannot separate events of a distance smaller than $a_0$, that is to localize the two frequencies and the transient phenomena.

Figure: Signal $f_2 = f_1 + \delta_1 + \delta_2$ and its Gabor transform with $a_0 = 0.05$
Limitation of the Short Time Fourier Transform

The STFT cannot separate events of a distance smaller than $a_0$, that is to localize the two frequencies and the transient phenomena.

Pioneer works on wavelets

- **Jean Morlet** research engineer at ELF Aquitaine discovered wavelets for solving signal processing problems arising from oil exploration.
- **Alex Grossmann** recognized in the Morlet wavelets something similar to coherent states formalism in quantum mechanics and developed an exact inversion formula for the wavelet transform.
- They developed the mathematics of the continuous wavelet transforms in their article: "Decomposition of Hardy Functions into Square Integrable Wavelets of Constant Shape" (1984)
"Gaborettes" vs Morlet wavelets

**Gabor** $\psi_{b,a}(t) = e^{it/a} \psi(t - b)$, (right) Morlet $\psi_{b,a}(t) = a^{-1/2} \psi\left(\frac{t-b}{a}\right)$

**Figure:** (Left) Gabor $\psi_{b,a}(t) = e^{it/a} \psi(t - b)$, (right) Morlet $\psi_{b,a}(t) = a^{-1/2} \psi\left(\frac{t-b}{a}\right)$

**Gabor** $\Rightarrow$ frequency modulation inside a constant window width  
**Wavelets** $\Rightarrow$ shape of $\psi_{b,a}$ doesn’t change, simply dilated or compressed.
The Continuous Wavelet Transform (CWT) – Definition

\[ Wf(a, b) = \int_{-\infty}^{+\infty} f(x) \psi_{a,b}(x) \, dx = \langle f, \psi_{\nu,b} \rangle, \quad a > 0, \ b \in \mathbb{R} \]

The analyzing functions or \textit{wavelets} are defined by:

\[ \psi_{a,b}(x) = \frac{1}{\sqrt{a}} \psi\left( \frac{x - b}{a} \right) \]
Wavelet family in physical space

Example: the Morlet wavelets

\[ \psi_{a,b}(x) = \frac{1}{\sqrt{a}} \psi\left(\frac{x - b}{a}\right) \]

with mother wavelet

\[ \psi(x) = \cos(x)e^{-10\pi x^2} \]

Figure: Morlet wavelets of scale: \( a = 1/2, 1, 2 \) (real part). The scale \( a \) gives the support size (inverse of a frequency), whereas \( b \) gives the position.
Wavelet analysis of the toy signal with Morlet wavelets

Figure: Signal $f_2$ (two notes + scratch) and its CWT
Wavelet definition

A function $\psi(x) \in L^1(\mathbb{R}) \cap L^2(\mathbb{R})$ is a wavelet if it satisfies the following admissibility condition:

$$C_\psi = \int_{-\infty}^{+\infty} \frac{\left| \hat{\psi}(\nu) \right|^2}{|\nu|} \, d\nu < \infty$$

which implies $\int_{-\infty}^{+\infty} \psi(x) \, dx = 0$ (and this is equivalent if $x\psi$ integrable).

Examples

1. The (complex) Morlet wavelet
   - Mother wavelet: $\psi(x) = e^{-\pi x^2} e^{10i\pi x}$
   - Its Fourier Transform: $\hat{\psi}(\nu) = e^{-\pi(\nu-5)^2}$

2. Gaussian derivatives
   - Mother wavelet: $\psi_n(x) = \frac{d^n}{dx^n} e^{-\pi x^2}, \quad n \geq 1$
     (for $n = 2$, $\psi_2$ is called the "Mexican Hat")
   - Its Fourier Transform: $\hat{\psi}_n(\nu) = (2i\pi \nu)^n e^{-\pi \nu^2}$
Wavelet analysis

A picture is worth a thousand words

Figure: Correlations with Morlet wavelets translated and dilated
Fourier Transform of wavelets

\[ \psi_{a,b}(x) = \frac{1}{\sqrt{a}} \psi \left( \frac{x - b}{a} \right) \quad \leftrightarrow \quad \hat{\psi}_{a,b}(\nu) = \sqrt{a} \hat{\psi}(a\nu) e^{-2i\pi b\nu} \]

Figure: Fourier Transform (modulus) of Morlet wavelets of scales \( a = 1/2, 1, 2 \). Wavelets behaves as band-pass filters around frequency \( \nu = \frac{\nu_0}{a} \), where \( \nu_0 \) is the peak wavenumber (max of \( \hat{\psi} \)). For the Morlet wavelet, \( \nu_0 = 5 \).
Equivalent definition

Let $f \in L^2(\mathbb{R})$. For all $a > 0$, $b \in \mathbb{R}$,

$$Wf(a, b) = \frac{1}{\sqrt{a}} \int_{-\infty}^{+\infty} f(x) \psi\left(\frac{x-b}{a}\right) \, dx$$

$$Wf(a, b) = \sqrt{a} \int_{-\infty}^{+\infty} \hat{f}(\nu) \hat{\psi}(a \nu) e^{2i\pi \nu b} \, d\nu$$

**Proof:** *From the Parseval formula*

$$Wf(a, b) = \langle f, \psi_{a,b} \rangle = \langle \hat{f}, \hat{\psi}_{a,b} \rangle$$

- In the time domain ($x$), $Wf(a, b)$ provides information on the signal $f$ around point $b$ in a vicinity of size $\sim a$.
- In the frequency domain ($\nu$), $Wf(a, b)$ provides information on the signal $\hat{f}$ around frequency $\sim \frac{1}{a}$.

$\Rightarrow$ Wavelet analysis is a time-scale analysis
Time-frequency resolution of wavelets

\[
\psi_{a,b}(x) = \frac{1}{\sqrt{a}} \psi\left(\frac{x - b}{a}\right) \quad \leftrightarrow \quad \hat{\psi}_{a,b}(\nu) = \sqrt{a} \hat{\psi}(a\nu)e^{-2\pi ib\nu}
\]

We suppose that \(\psi\) is analytic, \(\psi(0) = 0\) and \(\eta = \frac{1}{2\pi} \int_0^\infty \omega|\hat{\psi}(\omega)|^2d\omega\)

\[
\int_{-\infty}^{\infty} (t - b)^2|\psi_{a,b}(t)|^2dt \overset{t \leftarrow \frac{t-b}{a}}{=} \int_{-\infty}^{\infty} a^2 t^2 |\psi(t)|^2dt = a^2 \sigma_t^2
\]

\[
\frac{1}{2\pi} \int_0^{\infty} (\omega - \frac{\eta}{a})^2 |\hat{\psi}_{\xi, b}(\omega)|^2d\omega = \frac{1}{2\pi a^2} \int_0^{\infty} (\omega - \eta)^2 |\hat{\psi}(\omega)|^2d\omega = \frac{\sigma_\omega^2}{a^2}
\]

The energy spread of a wavelet time-frequency atom \(\psi_{a,b}\) corresponds to a Heisenberg box centered at \((b, \xi = \eta/a)\), of size \(a \sigma_t\) along time and \(\sigma_\omega/a\) along frequency. The area of the rectangle remains equal to \(\sigma_t \sigma_\omega\) at all scales but the resolution in time and frequency depends on \(a\). An analytic wavelet transform defines a local time-frequency energy density

\[
P_W f(b, \xi) = |Wf(a, b)|^2 = \left|Wf\left(\frac{\eta}{\xi}, b\right)\right|^2 \quad \text{(scalogram)}
\]
Heisenberg boxes of two wavelets $\psi_{a,b}$ and $\psi_{a_0,b_0}$

\[
\int_{-\infty}^{\infty} (t - b)^2 |\psi_{a,b}(t)|^2 \, dt = a^2 \sigma_t^2
\]

\[
\frac{1}{2\pi} \int_{0}^{\infty} \left( \omega - \frac{\eta}{a} \right)^2 |\hat{\psi}_{\xi,b}(\omega)|^2 \, d\omega = \frac{\sigma_\omega^2}{a^2}
\]
Inversion of the Continuous Wavelet Transform

Synthesis formula and energy conservation

Theorem (Calderón, Grossmann and Morlet)

Let \( \psi \in L^2(\mathbb{R}) \) be a real function such that

\[
C_\psi = \int_{-\infty}^{+\infty} \frac{|\hat{\psi}(\nu)|^2}{|\nu|} \, d\nu < \infty
\]

Any \( f \in L^2(\mathbb{R}) \) satisfies

\[
f(x) = \frac{1}{C_\psi} \int_{0}^{+\infty} \int_{-\infty}^{+\infty} Wf(a, b) \psi_{a,b}(x) \frac{da \, db}{a^2} \quad (*)
\]

and

\[
\int_{-\infty}^{+\infty} |f(x)|^2 \, dx = \frac{1}{C_\psi} \int_{0}^{+\infty} \int_{-\infty}^{+\infty} |Wf(a, b)|^2 \frac{da \, db}{a^2} \quad (**)\]
Proof (Synthesis formula): For a fixed $a$, the CWT can be written:

$$Wf(a, b) = \frac{1}{\sqrt{a}} \int_{-\infty}^{+\infty} f(x) \psi \left( \frac{x - b}{a} \right) \, dx = (f \ast \tilde{\psi}_a)(b)$$

where we have noted:

$$\psi_a(x) = \frac{1}{\sqrt{a}} \psi \left( \frac{x}{a} \right), \quad \tilde{\psi}_a(x) = \psi_a(-x)$$

The right integral $b(x)$ of $(\ast)$ can now be rewritten as a sum of convolutions:

$$b(x) = \frac{1}{C_\psi} \int_0^{+\infty} Wf(a, \cdot) \ast \psi_a(x) \, \frac{da}{a^2} = \frac{1}{C_\psi} \int_0^{+\infty} f \ast \tilde{\psi}_a \ast \psi_a(x) \, \frac{da}{a^2}$$

$$\hat{b}(\omega) = \frac{1}{C_\psi} \int_0^{+\infty} \hat{f}(\omega) \sqrt{a} \hat{\psi}^* (a \omega) \sqrt{a} \hat{\psi}(a \omega) \, \frac{da}{a^2} = \frac{\hat{f}(\omega)}{C_\psi} \int_0^{+\infty} |\hat{\psi}(a \omega)|^2 \, \frac{da}{a^2}$$

By the change of variable $\xi = a \omega$ we get

$$\frac{\hat{b}(\omega)}{C_\psi} = \frac{\hat{f}(\omega)}{C_\psi} \int_0^{+\infty} |\hat{\psi}(\xi)|^2 \, \frac{d\xi}{\xi} = \hat{f}(\omega)$$

The equality of their Fourier transform leads to $b = f$. QED
Inversion with a different synthesis wavelet

- **Decomposition** with an *analysing wavelet* $g$: $a > 0$, $b \in \mathbb{R}$,

$$W_g f(a, b) = \int_{-\infty}^{+\infty} f(x) \frac{1}{\sqrt{a}} \tilde{g} \left( \frac{x - b}{a} \right) \, dx$$

- **Synthesis** with a *reconstruction wavelet* $h$:

$$f(x) = \frac{2}{c_{gh}} \int_{0}^{+\infty} \int_{-\infty}^{+\infty} W_g f(a, b) \frac{1}{\sqrt{a}} h \left( \frac{x - b}{a} \right) \frac{da}{a^2} \, db$$

- **Cross-admissibility condition** on wavelets $g$ et $h$ ($g, h \in L^2(\mathbb{R})$):

$$c_{gh} = \int_{-\infty}^{+\infty} \frac{\tilde{g}(k) \hat{h}(k)}{|k|} \, dk < +\infty$$

**Remark**: In this case, only $h$ or $g$ has to be a zero mean function.
For a fixed $a$, the CWT is a convolution product:

$$Wf(a, b) = \frac{1}{\sqrt{a}} \int_{-\infty}^{+\infty} f(x) \psi \left( \frac{x - b}{a} \right) dx$$

$$= (f \ast \tilde{\psi}_a)(b)$$

where we have noted:

$$\tilde{\psi}_a(x) = \frac{1}{\sqrt{a}} \psi \left( -\frac{x}{a} \right)$$
Coding – In practice

\[ f \ast \hat{\psi}_a : b \mapsto Wf(a, b) \]

3D plot of Wavelet Transform

source: ataspinar.com
Examples and Interpretation

Example 1: pure cosine

If \( f \) is a pure cosine \( f(x) = \cos(2\pi kx) \), then

\[
Wf(a, b) = \left( e^{2i\pi kx} + e^{-2i\pi kx} \right) \frac{\psi_{a,b}(x)}{2} \quad \text{dx}
\]

\[
= \frac{1}{2} \left[ \hat{\psi}_{a,b}(k) + \hat{\psi}_{a,b}(-k) \right]
\]

\[
= \frac{\sqrt{a}}{2} \left[ \hat{\psi}(ak)e^{2i\pi kb} + \hat{\psi}(-ak)e^{-2i\pi kb} \right]
\]

- If the wavelet \( \psi \) is analytic complex:

\[
Wf(a, b) = \frac{\sqrt{a}}{2} \hat{\psi}(ak)e^{2i\pi kb}
\]

- If the wavelet \( \psi \) is real \( Wf(a, b) = \sqrt{a} \text{ Re} \left( \hat{\psi}(ak)e^{-2i\pi kb} \right) \)
Example 1: pure cosine

Pure cosine $f(x) = \cos(20\pi x)$ ($k = 10$)

Figure: CWT (modulus), using the Morlet wavelet (analytic complex)
Example 1: pure cosine

Pure cosine \( f(x) = \cos(20\pi x) \) \((k = 10)\)

Figure: CWT (modulus), using the Gaussian derivatives (real)
Examples and Interpretation

Example 2: a Dirac

If $f$ is a Dirac $f(x) = \delta(x - x_0)$ (pointwise measure supported by $x_0$), then:

$$ Wf(a, b) = \int_{-\infty}^{+\infty} \delta(x - x_0) \frac{\psi_{a,b}(x)}{\psi_{a,b}(x_0)} \, dx $$

$$ = \frac{1}{\sqrt{a}} \psi \left( \frac{x_0 - b}{a} \right) $$

Remark: At each scale $a, b \to Wf(a, b)$ is the wavelet of scale $a$ centered on $x_0$ (up to a symmetry).

Kévin Polisano

Wavelets and Applications
The Dyadic Wavelet Transform

For a fixed $a$, the CWT is a convolution product:

$$Wf(a, b) = \frac{1}{\sqrt{a}} \int_{-\infty}^{+\infty} f(x) \psi \left(\frac{x - b}{a}\right) \, dx$$

$$= (f \ast \tilde{\psi}_a)(b)$$

where we have noted:

$$\psi_a(x) = \frac{1}{\sqrt{a}} \psi \left(\frac{x}{a}\right), \quad \tilde{\psi}_a(x) = \psi_a(-x)$$
The Dyadic Wavelet Transform

For a fixed $a = 2^j$, the Dyadic Wavelet Transform is a convolution product:

$$Wf(2^j, b) = \frac{1}{\sqrt{2^j}} \int_{-\infty}^{+\infty} f(x) \psi\left(\frac{x - b}{2^j}\right) \, dx$$

$$d_j(b) = (f \ast \tilde{\psi}_j)(b)$$

where we have noted:

$$\psi_j(x) = \frac{1}{\sqrt{2^j}} \psi\left(\frac{x}{2^j}\right), \quad \tilde{\psi}_j(x) = \psi_j(-x)$$
The Dyadic Wavelet Transform

For a fixed $a = 2^j$, the Dyadic Wavelet Transform is a convolution product:

$$Wf(2^j, b) = \frac{1}{\sqrt{2^j}} \int_{-\infty}^{+\infty} f(x) \psi\left(\frac{x - b}{2^j}\right) \, dx$$

$$d_j(b) = (f \ast \psi_j)(b)$$

whose Fourier transform is

$$\hat{d}_j(\omega) = \hat{f}(\omega) \sqrt{2^j} \hat{\psi}^*(2^j \omega)$$
The Dyadic Wavelet Transform

Theorem (Littlewood-Paley, 1930)

If \( \sum_j |\hat{\psi}(2^j \omega)|^2 = 1 \) then

\[
f(x) = \sum_j 2^{-j} \int \mathcal{W}f(2^j, b) \psi_{2^j, b}(x) \, db
\]

Proof: Remark that

\[
\int \mathcal{W}f(2^j, b) \psi_{2^j, b}(x) \, db = d_j \ast \psi_j(x)
\]

then take the Fourier transform

\[
\sum_j 2^{-j} \hat{d}_j(\omega) \hat{\psi}_j(\omega) = \sum_j 2^{-j} \hat{f}(\omega) \sqrt{2^j} \hat{\psi}^*(2^j \omega) \sqrt{2^j} \psi(2^j \omega)
\]

\[
= \hat{f}(\omega) \sum_j |\hat{\psi}(2^j \omega)|^2 = \hat{f}(\omega)
\]

\[
\sum_j = 1
\]

Wavelet zoom
a local characterization of functions
Local characterization of regularity via the derivatives

"Smoothness" depends on the differentiability class to which a function belongs to. Among these 4 continuous ($C^0$) functions:

- $x \mapsto x^2$ is the only one differentiable everywhere and $C^\infty$
- $x \mapsto |x|$ is not differentiable at $x = 0$ (corner)
- $x \mapsto \sqrt{|x|}$ (cusp) and $\mathbb{1}_{[0,T]}$ (jump) have kind of "infinite gradient" at the singularity point $x = 0$
Prerequisite: Global regularity through Fourier coefficients

Lemma (Riemann-Lebesgue)

If $f$ is $L^1$ then the Fourier transform of $f$ satisfies

\[
\hat{f}(\omega) = \int f(x)e^{-i\omega x} \xrightarrow{|\omega|\to\infty} 0
\]

How fast the Fourier coefficients decrease?

For $f$ $p$ times continuously differentiable with bounded derivatives, since

\[\hat{f}(\omega) = \frac{1}{i\omega} \frac{d}{dx} \hat{f}(\omega)\]

then by iterating we get

\[\hat{f}(\omega) = \frac{1}{(i\omega)^p} \frac{d^p}{dx^p} f(\omega)\]

\[|\hat{f}(\omega)| \leq \frac{K}{|\omega|^p}\]

with $K = \sup \frac{d^p}{dx^p} f$
Prerequisite: Global regularity through Fourier coefficients

Conversely Fourier decay governs smoothness?

If \( \hat{f} \) is \( L^1 \) then \( f \in L^\infty \) and \( f \) is continuous.

**Proof:**

\[
|f(x)| \leq \frac{1}{2\pi} \int |e^{i\omega x} \hat{f}(\omega)| d\omega \leq \frac{1}{2\pi} \int |\hat{f}(\omega)| d\omega < +\infty
\]

which proves boundedness. As for continuity, consider a sequence \( y_n \to 0 \) and

\[
f(x - y_n) = \frac{1}{2\pi} \int e^{i\omega(x - y_n)} \hat{f}(\omega) \, d\omega
\]

The integrand converges pointwise to \( e^{i\omega x} \hat{f}(\omega) \) and is uniformly bounded in modulus by the integrable function \( \hat{f} \). Hence Lebesgue’s dominated convergence theorem applies and yields \( f(x - y_n) \to f(x) \) that is continuity in \( x \). \( \square \)
Prerequisite: Global regularity through Fourier coefficients

Theorem (Sufficient condition for differentiability of $f$ at order $p$)

A function $f$ is bounded and $p$ times continuously differentiable with bounded derivatives if

$$
\int_{-\infty}^{\infty} |\hat{f}(\omega)|(1 + |\omega|^p) \, d\omega < +\infty
$$

Proof: Knowing that $f^{(k)}(\omega) \mapsto (i\omega)^k \hat{f}(\omega)$, by the inversion formula

$$
|f^{(k)}(t)| = \left| \int_{-\infty}^{\infty} \hat{f}^{(k)}(\omega)e^{i\omega t} \, d\omega \right| \leq \int_{-\infty}^{\infty} |\hat{f}(\omega)| \cdot |\omega|^k \, d\omega < +\infty
$$

for any $k \leq p$, so $f^{(k)}$ is continuous and bounded. □

Corollary. If it exists a constant $K$ and $\epsilon > 0$ such that

$$
|\hat{f}(\omega)| \leq \frac{K}{1 + |\omega|^{p+1+\epsilon}}, \quad \text{then} \quad f \in C^p
$$

Credits: S. Mallat (Wavelet tour)
Prerequisite: Global regularity through Fourier coefficients

The decay of $|\hat{f}(\omega)|$ depends on the worst singular behavior of $f$

$f(x) = \begin{cases} 
-1 & \text{if } -\pi \leq x < 0 \\
1 & \text{if } 0 \leq x < \pi
\end{cases} = \sum_{n=1}^{+\infty} \frac{4}{\pi(2n-1)} \sin((2n-1)x)$

where $f$ is periodized. For $f = 1[-T,T] \Rightarrow |\hat{f}(\omega)| = o(|\omega|^{-1})$

**Wavelet zoom: Lipschitz regularity**

**Definition (Lipschitz regularity of order $\alpha$ of a function $f$)**

Let $\alpha \geq 0$ be the regularity parameter and $x_0 \in \mathbb{R}$. $f$ is pointwise Lipschitz–$\alpha$ at $x_0$, if there exist $C > 0$ and a polynomial $P_n$ of degree $n = \lfloor \alpha \rfloor$, such that

$$\forall h \in \mathbb{R}, \quad |f(x_0 + h) - P_n(h)| \leq C|h|^\alpha \tag{1}$$

$P_n$ is the Taylor expansion of $f$ at $x_0$. (If $0 < \alpha < 1$, $P_0(h) = f(x_0)$)

- $f$ is uniformly Lipschitz–$\alpha$ over $[a, b]$ if $f$ satisfies (1) for all $x_0 \in [a, b]$, with a constant $C$ independent of $x_0$.
- **Extension to negative $\alpha$ (distributions):** $f$ uniformly Lipschitz–$\alpha$ over $(a, b]$ if its primitive is Lipschitz–$(\alpha + 1)$ over $(a, b]$.
- The Lipschitz regularity of $f$ is the supremum of the $\alpha$ such that $f$ is Lipschitz–$\alpha$. 
Lipschitz–$\alpha$ functions

∀$h \in \mathbb{R}$, \[|f(x_0 + h) - f(x_0)| \leq C|h|^\alpha\]

Figure: The schematic diagram of Lipschitz–$\alpha$ functions

Credits: Li-Wei Liu & Hong-Ki Hong
Some examples

- A Lipschitz–\(\alpha\) function at \(x_0\), with \(0 < \alpha < 1\), is continuous, but a priori non differentiable.
- A \(C^1\) function in a neighborhood of \(x_0\) is Lipschitz–1 at \(x_0\).
- The Lipschitz regularity \(\alpha\) with \(n < \alpha < n + 1\) allows to classify regularities between \(C^n\) and \(C^{n+1}\).
- A bounded function is Lipschitz–0. For example the Heavyside function \(H(x) = 1\) if \(x \geq 0\) and 0 if \(x < 0\).
- The distribution \(\delta\) is Lipschitz–\((-1)\) (as the derivative of \(H\)).
- The function \(x \mapsto |x - x_0|^\alpha\) (\(0 < \alpha < 1\)) is Lipschitz–\(\alpha\)
- The function \(\sqrt{|\cos(2\pi x)|}\) is Lipschitz–\(\frac{1}{2}\).

Regularity measurements with wavelets

Let $\alpha \geq 0$ be fixed, $\psi$ a wavelet with compact support $\subset [-L, L]$, and $N > \alpha$ vanishing moments:

$$\int x^n \psi(x) \, dx = 0, \quad \text{for } 0 \leq n < N$$

**Remark:** a wavelet with $N$ vanishing moments is orthogonal to polynomials of degree $N - 1$.

**Polynomial Suppression.** Let $f$ Lipschitz-$\alpha$ at $x_0$, that is

$$f(x) = P_n(x - x_0) + \varepsilon(x - x_0) \quad \text{with} \quad |\varepsilon(x - x_0)| \leq |x - x_0|^\alpha$$

Since $\alpha < N$, the polynomial $P_N$ has degree at most $N - 1$. With the change of variable $y = (x - b)/a$, we verify that

$$WP_n(a, b) = \int_{-\infty}^{+\infty} P_n(x) \frac{1}{\sqrt{a}} \psi \left( \frac{x - b}{a} \right) \, dx = 0$$

Then,

$$Wf(a, b) = W\varepsilon(a, b)$$
Pointwise Lipschitz regularity and wavelet coefficients

Let $\alpha \geq 0$. One consider a wavelet $\psi$ of regularity $C^N$, with compact support $\text{supp} \, \psi \subset [-L, L]$, and $N \geq \alpha$ vanishing moments.

**Theorem (Jaffard, Estimation of the local regularity of $f$ at point $x_0$)**

If $f \in L^2(\mathbb{R})$ is Lipschitz–$\alpha \leq N$ at $x_0$, then $\exists A > 0$ such that

$$\forall (a, b) \in \mathbb{R} \times \mathbb{R}^+, \quad |Wf(a, b)| \leq A \, a^{\alpha + \frac{1}{2}} \left(1 + \left| \frac{b - x_0}{a} \right|^{\alpha} \right)$$

Conversely, if $\alpha < N$ is not an integer and there exist $A > 0$ and $\alpha' < \alpha$ such that

$$\forall (a, b) \in \mathbb{R} \times \mathbb{R}^+, \quad |Wf(a, b)| \leq A \, a^{\alpha + \frac{1}{2}} \left(1 + \left| \frac{b - x_0}{a} \right|^{\alpha'} \right)$$

then $f$ is Lipschitz-$\alpha$ at $x_0$. 
**Proof** of $\Rightarrow$

Since $f$ is Lipschitz–$\alpha$ at $x_0$, there exists a polynomial $P_N$ of degree $\lfloor \alpha \rfloor < N$ and $C > 0$ such that

$$|f(x) - P_N(x - x_0)| \leq C|x - x_0|^\alpha$$

Since $\psi$ has $N$ vanishing moments, we saw that $WP_n(a, b) = 0$, and thus

$$|Wf(a, b)| = \left| \int_{-\infty}^{\infty} [f(x) - P_N(x - x_0)] \psi_{a, b}(x) \, dx \right|$$

$$\leq \int C|x - x_0|^\alpha \frac{1}{\sqrt{a}} \left| \psi \left( \frac{x - b}{a} \right) \right| \, dx$$

The change of variable $y = \frac{x - b}{a}$ gives

$$|Wf(a, b)| \leq \sqrt{a} \int_{-\infty}^{\infty} C|ay + b - x_0|^\alpha |\psi(y)| \, dy$$
Proof of $\Rightarrow$

$$\left| Wf(a, b) \right| \leq \sqrt{a} \int_{-\infty}^{\infty} C\left( ay + b - x_0 \right) |\psi(y)| dy$$

Lemma: $|t + s|^\alpha \leq 2^\alpha (|t|^\alpha + |s|^\alpha)$

Proof: Let $m = \max(|t|, |s|)$ so that $|t + s| \leq |t| + |s| \leq 2m$. Then,

$$|t + s|^\alpha \leq (2m)^\alpha = 2^\alpha m^\alpha \leq 2^\alpha (|t|^\alpha + |s|^\alpha).$$

By the lemma,

$$\left| Wf(a, b) \right| \leq C2^\alpha \sqrt{a} \left( a^\alpha \int_{-\infty}^{\infty} |y|^\alpha |\psi(y)| dy + |b - x_0|^\alpha \int_{-\infty}^{\infty} |\psi(y)| dy \right)$$

$$\leq KM2^\alpha \frac{s^\alpha + \frac{1}{2}}{a} \left( 1 + \left| \frac{b - x_0}{a} \right|^\alpha \right)$$

with $M = \max \left( \int_{-\infty}^{\infty} |y|^\alpha |\psi(y)|, \int_{-\infty}^{\infty} |\psi(y)| dy \right)$. \qed
Cone of Influence

If $\text{supp } \psi = [-L, L]$, the cone of influence of $x_0$ in the time-scale space is the set of points such that $x_0 \in \text{supp } \psi_{a,b} = [b - La, b + La]$, that is

$$\Gamma(x_0) = \{(b, a) \in \mathbb{R} \times \mathbb{R}^* : |b - x_0| < La\}$$

If $f$ is Lipschitz-$\alpha$ at $x_0$, then $\exists A > 0$, such that for all $(b, a) \in \Gamma(x_0)$:

$$|Wf(a, b)| \leq A a^{\alpha + \frac{1}{2}}$$

and conversely for $\alpha$ non integer.

$\alpha$ is computed by the slope of the curve $\log a \rightarrow \log|Wf(a, b)|$
Wavelet Transform Modulus Maxima

References

Wavelet construction from the derivatives of a Gaussian

Let \( \theta(x) = \exp(-x^2/\sigma^2) \) the Gaussian Kernel and let considered

\[
\psi^N(x) \equiv \theta^{(n)}(x) = \left( \frac{d}{dx} \right)^N e^{-\frac{x^2}{\sigma^2}}
\]

The wavelet \( \psi^N \) has \( N \) vanishing moments.

Figure: The Gaussian \( \theta \ (n = 0) \) for \( \sigma = 1 \) and its two first derivatives: \( n = 1 \) is represented in (---) and \( n = 2 \) (the Mexican hat) in (···)
Multiscale differential operator

A wavelet $\psi$ has fast decay if

$$\forall m \in \mathbb{N}, \exists C_m \text{ such that } |\psi(x)| \leq \frac{C_m}{1 + |t|^m}, \forall t \in \mathbb{R}$$

Theorem (Multiscale differential operator)

A wavelet $\psi$ with fast decay has $N$ vanishing moments if and only if there exists $\theta$ with a fast decay such that

$$\psi(x) = (-1)^N \frac{d^N \theta}{dx^N}(x)$$

As a consequence

$$W_N f(a, b) = a^N \frac{d^N \theta}{db^N} (f \ast \check{\theta}_a)(b)$$

Moreover, $\psi$ has no more vanishing moments iff $\int \psi \neq 0$. 
Multiscale differential operator

Example

- The convolution $f \ast \tilde{\theta}_a$ averages $f$ over a domain proportional to $a$
- If the wavelet has only one vanishing moment: $\psi = -\theta'$ then $W_1(a, b) = a \frac{d}{db} (f \ast \tilde{\theta}_a)(b)$ has modulus maxima at sharp variation points of $f \ast \tilde{\theta}_a$
- If the wavelet has two vanishing moment: $\psi = -\theta''$ then $W_2(a, b) = a \frac{d^2}{db^2} (f \ast \tilde{\theta}_a)(b)$ corresponds to locally maximum curvatures
Wavelet Maxima Lines

- **Point of Modulus Maximum** are any point \((b_0, a_0)\) in the time-scale plan such that the curve \(b \mapsto |Wf(b, a_0)|\) is locally maximum at \(b = b_0\). This implies that

\[
\frac{\partial Wf(a_0, b_0)}{\partial b} = 0
\]

- **Maxima lines** is any connected curve \(a(b)\) in the scale-space plane \((b, a)\) along which all points are modulus maxima.

**Theorem (Hwang, Mallat)**

Suppose that \(\psi\) is \(C^N\) with a compact support and \(\psi = (-1)^N \theta^{(N)}\) with \(\int \theta \neq 0\). Let \(f \in L^1[b_0, b_1]\). If there exists \(a_0 > 0\) such that \(|Wf(a, b)|\) has no local maximum for \(b \in [b_0, b_1]\) and \(a < a_0\), then \(f\) is uniformly Lipschitz–\(N\) on \([b_0 + \epsilon, b_1 - \epsilon]\), for any \(\epsilon > 0\).
Wavelet Maxima Lines

Remarks

- This theorem implies that $f$ can be singular (not Lipschitz–1) at a point $x_0$ only if there is a sequence of wavelet maxima points $(b_k, a_k)_{k \in \mathbb{N}}$ that converges toward $x_0$ at fine scales:

$$\lim_{k \to +\infty} b_k = x_0 \quad \text{and} \quad \lim_{k \to +\infty} a_k = 0$$

- These modulus maxima points may or may not be along the same maxima line. This result guarantees that all singularities are detected by following the wavelet transform modulus maxima at fine scales.

Theorem (Hummel, Poggio, Yuille)

Let $\psi = (-1)^N \theta^{(N)}$ where $\theta$ is Gaussian. For any $f \in L^2$, the modulus maxima of $Wf(a, b)$ belongs to connected curves that are never interrupted when the scale decreases.
Wavelet Maxima Lines

Wavelets and Applications
Example: 2 cusps $f(x) = |x - 0.25|^\frac{1}{3} + |x - 0.7|^\frac{2}{3}$
Example: \( f(x) = |x - 0.25|^{1/3} + |x - 0.7|^{2/3} + \text{noise} \) (SNR=0.01)
Practical estimation of $\alpha$

$f$ is uniformly Lipschitz–$\alpha$ in the neighborhood of $x_0$ iff there exists $A > 0$ such that each modulus maximum $(b, a)$ in the cone satisfies

$$|Wf(a, b)| \leq A a^{\alpha + \frac{1}{2}}$$

which is equivalent to

$$\log_2 |Wf(a, b)| \leq \log_2 A + \left( \alpha + \frac{1}{2} \right) \log_2 a$$

$\Rightarrow$ The Lipschitz regularity at $x_0$ is the maximum slope of $\log_2 |Wf(a, b)|$ as a function of $\log_2 a$ along the maxima lines converging to $x_0$
Practical estimation of $\alpha$

**Example**

Figure: The full line gives the decay along the maxima line that converges to the first jump, and the dashed line to the first cusp.

Take home message

- Vanishing moments up to order $N$ make the wavelet $\psi$ blind to polynomial of degree $\leq N$ (smooth part of the signal), leading to better detections of singularities.

- If the function is Lipschitz–$\alpha$, then the amplitude of the wavelet coefficients are going to decay very fast to zero when the scale goes to zero (all the more that $\alpha$ is high).

- A remarkable aspect is the reverse: if we know this property, then we can characterize the pointwise regularity of the function at any point.

- All singularities are detected by following the wavelet transform modulus maxima at fine scale.

- The Lipschitz regularity at every point can be retrieved by measuring the maximum slop of the decay of $\log_2|Wf(a, b)|$.

- The wavelet-based estimation of the Lipschitz regularity enables to recover the self-similarity exponent of fractals.
The 2D Continuous Wavelet Transform
Bidimensional Continuous Wavelet Transform

1. 2D Wavelets
2. Directional Continuous Wavelet Transform, inversion formula
3. Isotropic Wavelet Transform
4. A wavelet for image analysis: the "Canny" wavelets
2D Fourier Transform

The bidimensional Fourier transform of a function $f$ integrable on $\mathbb{R}^2$ is defined by:

$$\hat{f}(k) = \iint_{\mathbb{R}^2} f(x) e^{-2i\pi k \cdot x} \, dx, \quad \forall k \in \mathbb{R}^2$$

If $f \in L^2(\mathbb{R}^2)$, the inversion formula is given by:

$$f(x) = \iint_{\mathbb{R}^2} \hat{f}(k) e^{2i\pi k \cdot x} \, dk$$

and the energy conservation writes:

$$\iint_{\mathbb{R}^2} |f(x)|^2 \, dx = \iint_{\mathbb{R}^2} |\hat{f}(k)|^2 \, dk$$
2D Fourier Transform
Definition of 2D wavelets

$\psi \in L^1(\mathbb{R}^2) \cap L^2(\mathbb{R}^2)$ is a wavelet if it satisfies the admissibility condition:

$$c_\psi = \iint_{\mathbb{R}^2} \frac{|\hat{\psi}(k)|^2}{\|k\|^2} \, dk < +\infty$$

which implies (and is equivalent provided $\psi$ has sufficient decay at infinity):

$$\iint_{\mathbb{R}^2} \psi(x) \, dx = 0$$

In practice, one usually needs that $\psi$ has $p$ vanishing moments:

$$\iint_{\mathbb{R}^2} x_1^{\alpha_1} x_2^{\alpha_2} \psi(x_1, x_2) \, dx_1 \, dx_2 = 0, \quad \forall \alpha_1, \alpha_2 \in \mathbb{N} \text{ s.t. } \alpha_1 + \alpha_2 \leq p - 1$$

**Remark**: this means that the Fourier transform of the wavelet should behave as $\|k\|^p$ when $k \to 0$ in Fourier domain.
2D Wavelet family

Let $\psi(x)$ be an admissible wavelet. The wavelet family is defined by dilation, rotation, and translation from $\psi$:

$$
\psi(a,b,\theta)(x) = \frac{1}{a} \psi \left( R_{-\theta} \left( \frac{x - b}{a} \right) \right)
$$

with $b \in \mathbb{R}^2$ the translation parameter, $a$ the positive scale and $R_{-\theta}$ the rotation of angle $\theta$ in $\mathbb{R}^2$, corresponding to matrix

$$
R_{-\theta} = \begin{pmatrix}
\cos \theta & \sin \theta \\
-\sin \theta & \cos \theta
\end{pmatrix}
$$

Example (Anisotropic Morlet Wavelet)

Let $u = (\cos \alpha, \sin \alpha)$ the unitary vector of direction $\alpha$. The (complex) Morlet wavelet is:

$$
\psi(x) = e^{-\pi \|x\|^2} e^{10i\pi x \cdot u}
$$
Isotropic wavelets

Example (Iterated Laplacian of Gaussian)

For $n \geq 1$, the wavelet $h_{2n}$ is defined by:

$$h_{2n}(x) = (-1)^n \left( \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \right)^n e^{-\pi\|x\|^2}$$

Its Fourier transform is given by:

$$\hat{h}_{2n}(k) = 4^n \pi^{2n} \|k\|^{2n} e^{-\pi\|k\|^2}$$

For $n = 2$, $h_2$ is the Laplacian of Gaussian, popular in computer vision, also called the Mexican hat.

Remark: the wavelet $h_{2n}$ has exactly $2n$ vanishing moments. The maximum of its Fourier transform $\hat{h}_{2n}$ is achieved for $k_0 = \sqrt{2n}$. 
Isotropic wavelets

Example (Iterated Laplacian of Gaussian)

- Wavelet $h_2(x, y)$ (Mexican hat) and 1D section:

- 1D section in physical and Fourier space of the wavelet $h_8$
2D directional continuous wavelet transform

Let $\psi$ be a 2D wavelet.

The directional wavelet transform of a given function $f \in L^2(\mathbb{R}^2)$ is defined by:

$$Wf(a, b, \theta) = \frac{1}{a} \int_{\mathbb{R}^2} f(x) \psi_a b \theta(x) \, dx$$

Applying Parseval formula, it writes:

$$Wf(a, b, \theta) = a \int_{\mathbb{R}^2} \hat{f}(k) \tilde{\psi}(a R_{-\theta} k) e^{2i\pi k \cdot b} \, dk$$
Inversion formula

The function $f$ can be reconstructed by:

$$f(x) = \frac{1}{c_{\psi}} \int_{0}^{+\infty} \int_{0}^{2\pi} \int_{\mathbb{R}^2} Wf(a, b, \theta) \psi_{(a, b, \theta)}(x) \frac{da}{a^3} \ d\theta \ db$$

with

$$c_{\psi} = \int_{\mathbb{R}^2} \frac{|\hat{\psi}(k)|^2}{\|k\|^2} \ dk$$

The energy conservation writes:

$$\int_{\mathbb{R}^2} |f(x)|^2 \ dx = \frac{1}{c_{\psi}} \int_{0}^{+\infty} \int_{0}^{2\pi} \int_{\mathbb{R}^2} |Wf(a, b, \theta)|^2 \frac{da}{a^3} \ d\theta \ db$$
Inversion formula with a different wavelet

Let \( f(x) \in L^2(\mathbb{R}^2) \).

Wavelet decomposition of \( f(x) \) with an analysing wavelet \( g \):

\[
W_g f(a, b, \theta) = \int_{\mathbb{R}^2} f(x) \frac{1}{a} \bar{g} \left( R_{-\theta} \left( \frac{x - b}{a} \right) \right) \, dx
\]

Synthesis with a reconstruction wavelet \( h \):

\[
f(x) = \frac{1}{c_{gh}} \int_0^{+\infty} \int_0^{2\pi} \int_{\mathbb{R}^2} W_g f(a, b, \theta) \frac{1}{a} h \left( R_{-\theta} \left( \frac{x - b}{a} \right) \right) \, \frac{da}{a^3} \, d\theta \, db
\]

Cross admissibility condition on functions \( g, h \in L^2(\mathbb{R}^2) \):

\[
c_{gh} = \int_{\mathbb{R}^2} \frac{\hat{g}(k)\hat{h}(k)}{\|k\|^2} \, dk < +\infty
\]
Classical examples

Wavelet constructed from the Gaussian $G(x) = e^{-\pi \|x\|^2}$

- Wavelet transform with an isotropic wavelet
  - $g(x) = h(x) = \Delta G(x)$ (Mexican hat)
  - $g(x) = G(x)$ ($g$ is not a wavelet) and $h(x) = \Delta G(x)$

- Wavelet transform with a vector wavelet $g(x) = \nabla G(x)$ (Canny multi-scale detector)
Isotropic Wavelet Transform

When the wavelet is real, isotropic (i.e. rotation invariant \( \psi(x) = h(\|x\|) \)), the wavelet transform of \( f \) comes down:

\[
Wf(a, b) = \frac{1}{a} \int \int_{\mathbb{R}^2} f(x) \psi \left( \frac{x - b}{a} \right) dx
\]

\[\Rightarrow\] the integral on \( \theta \) disappears

From Parseval equality, it writes:

\[
Wf(a, b) = a \int \int_{\mathbb{R}^2} \hat{f}(k) \overline{\hat{\psi}(ak)} e^{2i\pi k \cdot b} dk
\]

\[\Rightarrow\] the wavelet transform acts as a filter on the Fourier transform of \( f \) around the frequency \( \frac{k_0}{a} \).
If $\psi$ is admissible, one has the energy conservation:

$$\int \int |f(x)|^2 \, dx = \frac{1}{c_\psi} \int_0^{+\infty} \int \int |Wf(a, b)|^2 \frac{da}{a^3} \, db$$

and the synthesis formula:

$$f(x) = \frac{1}{c_\psi} \int_0^{+\infty} \int \int Wf(a, b) \psi_{a,b}(x) \frac{da}{a^3} \, db$$
The Canny multiscale detector for image processing

Let $\Theta$ be a smoothing kernel such that:

- $\int_{\mathbb{R}^2} \Theta = 1$
- $\Theta \geq 0$
- $\Theta$ isotropic or $\Theta(x, y) = \Theta_1(x)\Theta_2(y)$

Example (Gaussian)

$\Theta(x) = G(x) = e^{-\pi \|x\|^2}$ a smoothing kernel isotropic and tensorial

Directional Wavelets

$$\Psi(x) = \nabla \Theta(x) = (\psi^1, \psi^2)$$

$$\psi^1 = -\frac{\partial \Theta}{\partial x_1} \quad \text{and} \quad \psi^2 = -\frac{\partial \Theta}{\partial x_2}$$

Wavelets in the direction $\varphi \Rightarrow \psi^\varphi = \cos \varphi \frac{\partial G}{\partial x_1} + \sin \varphi \frac{\partial G}{\partial x_2} = \vec{\varphi} \cdot \nabla G$$
The Canny multiscale detector for image processing

Decomposition: computation of the vector wavelet transform

\[ Wf(a, b) = (W^1f(a, b), W^2f(a, b)) \]

- \( W^1f(a, b) = \int \int_{\mathbb{R}^2} f(x) \frac{1}{a} \psi^1 \left( \frac{x - b}{a} \right) \, dx \rightarrow \text{vertical singularities} \)
- \( W^2f(a, b) = \int \int_{\mathbb{R}^2} f(x) \frac{1}{a} \psi^2 \left( \frac{x - b}{a} \right) \, dx \rightarrow \text{horizontal singularities} \)

Interpretation:

\[ Wf(a, b) = a \nabla \left( f \ast \frac{1}{a} \Theta \left( \frac{x}{a} \right) \right)(b) \]

\( Wf \) represents the gradient of the image, smoothed by \( \Theta \) at scale \( a \)
Proof: Let define \( L(x) = -\frac{x}{a} \), \( \tilde{\Theta}_a = \frac{1}{a} \Theta \circ L \), \( \tilde{\psi}_a^k(x) = \frac{1}{a} \psi^k \left( -\frac{x}{a} \right) \).

\[
W^k f(a, b) = \int\int_{\mathbb{R}^2} f(x) \frac{1}{a} \psi^k \left( \frac{x - b}{a} \right) \, dx = (f \ast \tilde{\psi}_a^k)(b)
\]

By the chain rule \( \frac{\partial}{\partial x_k} (\Theta \circ L)(x) = \frac{\partial \Theta}{\partial x_k} (L(x)) \frac{\partial L}{\partial x_k} (x) \) hence

\[
\tilde{\psi}_a^k(x) = -\frac{1}{a} \frac{\partial \Theta}{\partial x_k} \left( -\frac{x}{a} \right) = a \frac{\partial}{\partial x_k} \left( \frac{1}{a} \Theta \circ L \right)(x) = a \frac{\partial \tilde{\Theta}_a}{\partial x_k}
\]

\[
(f \ast \tilde{\psi}_a^k)(b) = a \int\int f(x) \frac{\partial \tilde{\Theta}_a}{\partial x_k} (b - x) \, dx
\]

\[
= \frac{\partial}{\partial b_k} \int\int f(x) \tilde{\Theta}_a(b - x) \, dx
\]

\[
= \frac{\partial}{\partial b_k} (f \ast \tilde{\Theta}_a)(b)
\]

\[
\left( W^1 f(a, b), W^2 f(a, b) \right) = a \left( \frac{\partial}{\partial b_1} (f \ast \tilde{\Theta}_a)(b), \frac{\partial}{\partial b_2} (f \ast \tilde{\Theta}_a)(b) \right) = a \nabla (f \ast \tilde{\Theta}_a)(b) \quad \blacksquare
\]
Multiscale detector and directional wavelet transform

If $\Theta$ is isotropic, one has

$$\frac{\partial \Theta}{\partial x_1}(R^{-\theta} x) = \cos \theta \frac{\partial \Theta}{\partial x_1}(x) + \sin \theta \frac{\partial \Theta}{\partial x_2}(x)$$

Then,

$$W_{\psi_1} f(a, b, \varphi) = \vec{\varphi} \cdot W f(a, b) \rightarrow \text{singularities in the direction } \vec{\varphi}^\perp$$

where $W_{\psi_1} f$ is the directional wavelet transform of $f$ with $\psi_1$ as analyzing wavelet.

One can write:

$$\begin{pmatrix} W_{\psi_1} f(a, b, \varphi) \\ W_{\psi_2} f(a, b, \varphi) \end{pmatrix} = \begin{pmatrix} \cos \varphi & \sin \varphi \\ -\sin \varphi & \cos \varphi \end{pmatrix} \begin{pmatrix} W^1 f(a, b) \\ W^2 f(a, b) \end{pmatrix}$$

In vector formulation:

$$W_{\nabla \Theta} = R_{-\varphi} W$$

$\Rightarrow$ will provide a reconstruction formula for the multiscale detector!
Inversion of the multiscale detector (Le Cadet, PhD 2004)

\[ f(x) = \frac{\pi}{C_{\psi_1}} \int_{a>0} \frac{da}{a^3} \int_{\mathbb{R}^2} Wf(b, a) \cdot \Psi_{a,b}(x) \, db \]

with \( C_{\psi_1} = \pi^2 \) for \( \Theta = G \).

**Proof:** The reconstruction formula of the directional wavelet transform with wavelet \( \psi^1 \) gives:

\[ f(x) = \frac{1}{C_{\psi_1}} \int_0^{2\pi} \int_0^{+\infty} \int_{\mathbb{R}^2} W_{\psi_1} f(a, b, \theta) \frac{1}{a} \psi^1 \left( R^{-\theta} \left( \frac{x - b}{a} \right) \right) \, d\theta \frac{da}{a^3} \, db \]

Replacing \( W_{\psi_1} f(a, b, \theta) \) by its definition:

\[ f(x) = \frac{1}{C_{\psi_1}} \int_0^{2\pi} \int_0^{+\infty} \int_{\mathbb{R}^2} \left[ \cos \theta \, W^1 f(a, b) + \sin \theta \, W^2 f(a, b) \right] \frac{1}{a} \frac{\partial \Theta}{\partial x_1} \left( R^{-\theta} \left( \frac{x - b}{a} \right) \right) \, d\theta \frac{da}{a^3} \, db \]
If $\Theta$ is isotropic, one has:

$$ \frac{\partial \Theta}{\partial x_1} (R^{-\theta} x) = \cos \theta \frac{\partial \Theta}{\partial x_1} (x) + \sin \theta \frac{\partial \Theta}{\partial x_2} (x) $$

then

$$ f(x) C_{\psi_1} = \int_{a>0} \frac{da}{a^3} \int_{\mathbb{R}^2} db \int_0^{2\pi} d\theta \cos^2 \theta \ W^1 f(a, b) \frac{1}{a} \frac{\partial \Theta}{\partial x_1} \left( \frac{x-b}{a} \right) $$

$$ + \int_{a>0} \frac{da}{a^3} \int_{\mathbb{R}^2} db \int_0^{2\pi} d\theta \sin^2 \theta \ W^2 f(a, b) \frac{1}{a} \frac{\partial \Theta}{\partial x_2} \left( \frac{x-b}{a} \right) $$

$$ + \int_{a>0} \frac{da}{a^3} \int_{\mathbb{R}^2} db \int_0^{2\pi} d\theta \cos \theta \sin \theta \ W^1 f(a, b) \frac{1}{a} \frac{\partial \Theta}{\partial x_2} \left( \frac{x-b}{a} \right) $$

$$ + \int_{a>0} \frac{da}{a^3} \int_{\mathbb{R}^2} db \int_0^{2\pi} d\theta \cos \theta \sin \theta \ W^2 f(a, b) \frac{1}{a} \frac{\partial \Theta}{\partial x_1} \left( \frac{x-b}{a} \right) $$

Since $\int_0^{2\pi} \cos^2 \theta \ d\theta = \int_0^{2\pi} \sin^2 \theta \ d\theta = \pi$ and $\int_0^{2\pi} \cos \theta \sin \theta \ d\theta = 0$ then

$$ f(x) = \frac{\pi}{C_{\psi_1}} \int_{a>0} \frac{da}{a^3} \int_{\mathbb{R}^2} db \left[ W^1 f(a, b) \psi_{a,b}^1 (x) + W^2 f(a, b) \psi_{a,b}^2 (x) \right] \square $
Energy conservation formula

The vector $\mathcal{W}f(a, b)$ should be represented in modulus-orientation:

\[
Mf(a, b) = \|\mathcal{W}f(a, b)\| \quad \text{Modulus}
\]
\[
Af(a, b) = \text{Arg}(\mathcal{W}f(a, b)) \quad \text{Orientation}
\]

The energy conservation (with an isotropic kernel $\Theta$) writes:

\[
\iint_{\mathbb{R}^2} |f(x)|^2 dx = \frac{\pi}{C_\psi} \int_{a>0} \frac{da}{a^3} \iint_{\mathbb{R}^2} (Mf(a, b))^2 db
\]

Example (Application: edge detection in 2D images)

1. **Edge points at scale** $a$ **are points where** $b \mapsto Mf(a, b)$ **is locally maximum in the direction** $Af(a, b)$.

2. **Estimation of the maxima lines** linking edge points through scales $a$. The **tops** of these maxima lines ($a \to 0$) finally constitute the edge points of the image.

3. **Computation of the Lipschitz regularity** at any edge point.
Application: edge detection in 2D images

Detection and classification of edges of a regular image, regular outside regular singularity lines.

The edge is characterized by a singularity in the intensity, in the direction of the gradient $\vec{\nabla} I$.

Along the edge, i.e. in the orthogonal direction of the gradient, the regularity is maximal.

Remark: In practice one will consider $\nabla (I \ast \frac{1}{a^2} G(\frac{x}{a}))$, which correspond to wavelet coefficients of $I$ with a wavelet Gaussian gradient.
Application: edge detection in 2D images

Edge Model (Canny 86)

A point \((x_0, y_0)\) of an image is an edge point if at this point the gradient modulus of the intensity, smoothed by a kernel \(\theta_a\), \(|\nabla(I \ast \theta_a)|\), is locally maximum in the direction of the gradient \(\nabla(I \ast \theta_a)\).

Variation of the intensity of a Gaussian distribution; where are the edges?
Application: edge detection in 2D images

New Edge Model (Mallat-Zhong, Mallat-Hwang 92, Le Cadet 2004)

$f$ image smoothed by a kernel $\theta_a$ of scale $a$ with $0 < a < a_{max}$: $g_a = f \ast \theta_a$. If there exists a connected curve through scales, along which all points are local maxima in the gradient direction $\nabla g_a$, the limit $(x_0, y_0)$ of this curve at small scales is an edge point.

Large scale
Application: modulus of the wavelet transform local max.

Figure: Edge points (top), wavelet coefficients maps at fixed scale (bottom) of a X-Ray image
Practice of the maxima line construction in 2D

1. Map of modulus maxima (in the gradient direction) at each scale.
2. Two modulus maxima between two successive scales are linked if they are neighbors in the gradient direction.
Practice of the maxima line construction in 2D

1. Let \( Mf(x_0, y_0, a_{dep}) \) be a modulus maximum at scale \( a_{dep} \).
2. One consider, the 9 modulus \( Mf(x_0(\pm1), y_0(\pm1), a_{dep+1}) \).
3. One links with the maximum modulus that has the angle \( Af(x_1, y_1, a_{dep+1}) \) closest to \( Af(x_0, y_0, a_{dep}) \).
The dyadic wavelet transform

The scale varies along the dyadic sequence \( \{2^j\}_{j \in \mathbb{Z}} \). Let \( 1 \leq k \leq 2 \)

\[
\psi^k(x) = -\frac{\partial \theta}{\partial x_k}, \quad \psi^k_{2^j}(x) = \frac{1}{2^j} \psi^k \left( \frac{x}{2^j} \right), \quad \tilde{\psi}^k_{2^j}(x) = \psi^k_{2^j}(-x)
\]

The dyadic wavelet transform at \( b = (b_1, b_2) \) is:

\[
W^k(2^j, b) = \langle f, \psi^k_{2^j}(\cdot - b) \rangle = f * \tilde{\psi}^k_{2^j}(b)
\]

Let \( \theta_{2^j}(x) = 2^{-j} \theta(2^{-j} x) \) and \( \tilde{\theta}_{2^j}(x) = \theta_{2^j}(-x) \). The wavelet transform components are proportional to the gradient of \( f \) smoothed by \( \tilde{\theta}_{2^j} \):

\[
\begin{pmatrix}
W^1 f(2^j, b) \\
W^2 f(2^j, b)
\end{pmatrix} = 2^j \begin{pmatrix}
\frac{\partial}{\partial b_1} (f * \tilde{\theta}_{2^j})(b) \\
\frac{\partial}{\partial b_2} (f * \tilde{\theta}_{2^j})(b)
\end{pmatrix} = 2^j \nabla (f * \tilde{\theta}_{2^j})(b)
\]
The dyadic wavelet transform

- The modulus of this gradient vector is proportional to the wavelet transform modulus:

\[ M_f(2^j, b) = \sqrt{|W^1 f(2^j, b)|^2 + |W^2 f(2^j, b)|^2} \]

- The angle \( A_f(2^j, b) \) of the wavelet transform vector:

\[
A_f(2^j, b) = \begin{cases} 
\alpha(b) & \text{if } W^1 f(2^j, b) \geq 0 \\
\pi + \alpha(b) & \text{if } W^2 f(2^j, b) \geq 0
\end{cases}
\]

\[ \alpha(b) = \tan^{-1}\left[ \frac{W^2 f(2^j, b)}{W^1 f(2^j, b)} \right], \quad n_j(b) = (\cos A_f(2^j, b), \sin A_f(2^j, b)) \]

- An edge point \( b_0 \) at the scale \( 2^j \): \( M_f(2^j, b) \) is locally maximum at \( b = b_0 \) when \( b = b_0 + \lambda n_j(b_0) \) and \( |\lambda| \) small enough.

- The level sets of \( g(x) \) are the curves \( x(s) \) where \( g(x(s)) \) is constant. If \( \tau \perp x(s) \) then

\[
\frac{\partial x(s)}{\partial s} = \nabla g \cdot \tau = 0
\]
The dyadic wavelet transform

- The level set property applied to $g = f * \hat{\theta}_{2^j}$ proves that a maximum point $b_0$ the vector $n_j(b_0)$ of angle $\angle f(2^j, b_0)$ is perpendicular to the level set of $f * \hat{\theta}_{2^j}$ going through $b_0$.

- If the intensity profile remains constant along an edge, then the inflection points (maxima points) are along a level set. The intensity profile of an edge may not be constant but its variations are often negligible over a neighborhood of size $2^j$ for a small scale $2^j$. The tangent of the maxima curve is then nearly perpendicular to $n_j(b_0)$.
Reconstruction of edge curves

Application: characterization of the singularities

Regularity of edge curves

Let $0 \leq \alpha < 1$. $f(x, y)$ Lipschitz-$\alpha$ at $(x_0, y_0)$ if $\exists A$ s.t $\forall h = (h_1, h_2)$,

$$|f(x_0 + h_1, y_0 + h_2) - f(x_0, y_0)| \leq A\|h\|^\alpha$$

On a curve of discontinuity, the estimation of the regularity reduces to the one dimensional case. $f$ is uniformly Lipschitz-$\alpha$ inside $\Omega$ iff

$$\forall (x, y) \in \Omega, \forall j, \quad |Mf(x, y, 2^j)| \leq A \cdot 2^{j(\alpha+1)}$$
Computation of the Lipschitz regularity

The Lipschitz regularity is evaluated at each edge point, by computing the slope of \( \log Mf(x_c, y_c, a) = g(\log a) \)

Figure: Top: original images; Bottom: edge points (the colors represent the regularity parameter)
Examples

Figure: Edge detection on two X-rays of vertebra
Reconstruction from edges

Image approximations can be computed by projecting the image on the space generated by wavelets on the modulus maxima support. Let \( \Lambda \) be the set of all modulus maxima points \((2^j, b)\), \( n \) is the unit vector in the direction \( Af(2^j, b) \) and

\[
\psi_{2^j, b}(x) = 2^{2j} \frac{\partial^2 \theta_{2j}(x - b)}{\partial n^2}
\]

Since the wavelet modulus \( Mf(2^j, b) \) has a local maximum at \( b \) in the direction of \( n \) then \( \langle f, \psi_{2^j, b} \rangle = 0 \).

A modulus maxima approximation \( f_\Lambda \) can be computed as an orthonormal projection of \( f \) on the space generated by the family of maxima wavelets \( \{\psi_{2^j, b}^k\} (2^j, b) \in \Lambda, 1 \leq k \leq 3 \):

\[
f_\Lambda = L^{-1}(Lf), \quad Ly = \sum_{(2^j, b) \in \Lambda} \sum_{k=1}^{2} \langle y, \psi_{2^j, b}^k \rangle \psi_{2^j, b}^k
\]

The 1D Discrete Wavelet Transform
From the CWT to the DWT

\[ \psi_a(x) = \frac{1}{\sqrt{a}} \psi \left( \frac{x}{a} \right) \]

local matching of wavelet and signal leads to a large transform value
Scaling function

When $Wf(a, b)$ is known only for $a < a_0$, to recover $f$ we need a complement of information that corresponds to $Wf(a, b)$ for $a > a_0$. This is obtained by introducing a scaling function $\phi$ that is an aggregation of wavelets at scales larger than 1:

$$
|\hat{\phi}(\omega)|^2 = \int_1^{+\infty} |\hat{\psi}(a \omega)|^2 \frac{da}{a} = \int_\omega^{+\infty} \frac{|\hat{\psi}(\xi)|^2}{|\xi|} d\xi
$$

and the complex phase of $\hat{\phi}(\omega)$ can be arbitrarily chosen. One can verify that $\|\phi\| = 1$, and from admissibility condition that $\lim_{\omega \to 0} |\hat{\phi}(\omega)|^2 = C_\psi$. The scaling function therefore can be interpreted as the impulse response of a low-pass filter. Let us denote $\phi_a(x) = a^{-1/2} \phi(x/a)$ and $\check{\phi}_a(x) = \phi_a^*(-x)$. The low-frequency approximation of $f$ at scale $a$ is $Lf(a, b) = f * \check{\phi}_a(b)$ and it can be shown that:

$$
f(x) = \frac{1}{C_\psi a_0} Lf(a_0, \cdot) * \phi_{a_0}(x) + \frac{1}{C_\psi} \int_0^{a_0} Wf(a, \cdot) * \psi_a(x) \frac{da}{a^2}
$$
From the CWT to the DWT

- We need to discretize the CWT for numerical applications
- It requires to choose a sampling grid, that is a discrete lattice

\[ \Gamma = \{ a_j, b_{j,k}, j, k \in \mathbb{Z} \} \]

- Noting \( \psi_{j,k} = \psi_{a_j,b_{j,k}} \) and \( \tilde{\psi}_{j,k} \) explicitly derived from \( \psi_{j,k} \) we want:

\[ f = \sum_{j,k \in \mathbb{Z}} \langle f, \psi_{j,k} \rangle \tilde{\psi}_{j,k} \]

- The dyadic grid corresponds to the choice \( a_j = 2^{-j} \) and \( b_{j,k} = k2^{-j} \)

\[ \psi_{j,k}(x) = 2^{j/2} \psi(2^j x - k), \quad j, k \in \mathbb{Z} \]

\[ \Rightarrow \text{mostly leads to frames not bases.} \]
From the CWT to the DWT
From the CWT to the DWT

Definition (Frame)

\[ \{ \psi_{j,k} \} \text{ is a frame in the Hilbert space } \mathcal{H} \text{ if there exists } B \geq A > 0 \text{ such that} \]

\[ A \| f \|^2 \leq \sum_{j,k \in \mathbb{Z}} |\langle f, \psi_{j,k} \rangle|^2 \leq B \| f \|^2 \]

- \( A, B \) are the frame bounds
- \( A = B \neq 1 \) is a tight frame
- \( A = B = 1 \) and \( \| \psi_{j,k} \| = 1 \) is an orthonormal basis

\[ \Rightarrow \text{Given a wavelet } \psi \text{ we need to find lattice } \Gamma \text{ such that } \{ \psi_{j,k} \} \text{ is a "good frame" that is } \frac{A}{B} \approx 1. \]

(Example)

Mexican hat and Morlet wavelets give good nontight frames for a dyadic lattice, adapted to geometry.
From frames to bases

Questions

- Can we reconstruct any function of Hilbert space from the discrete subset of wavelet coefficients?
- Is there a basis of orthogonal wavelets on $L^2(\mathbb{R})$?
- How can we construct such wavelets? With specific properties: regular, with compact support, ...
- Is there a fast algorithm to compute them?

Advantage of the decomposition

The Haar decomposition of a function $f \in L^2(0, 1)$ finally writes:

$$f = c_0 + \sum_{j=0}^{\infty} \sum_{k=0}^{2^j-1} d_{j,k} \psi_{j,k}$$

with

$$c_0 = \langle f, \varphi \rangle = \int_0^1 f(x) \, dx, \quad d_{j,k} = \langle f, \psi_{j,k} \rangle = \int_0^1 f(x) \psi_{j,k}(x) \, dx$$

Local smoothness characterization

(i) if $f \in C^1(I_{j,k})$ then $|d_{j,k}| \leq C \, 2^{-3j/2}$

(ii) if $f \in C^\alpha(x_0)$ i.e. $|f(x) - f(x_0)| \leq k|x - x_0|^\alpha$ ($0 < \alpha < 1$) then

$$|d_{j,k}| \leq C \, 2^{-j(\alpha+1/2)}$$

⇒ Useful property for compression!
Proof of (i)

For fixed $j \geq 0$ and $k \in \{0, \ldots, 2^j - 1\}$, let $l_{j,k} := [k2^{-j}, (k + 1)2^{-j}]$. 

$$\text{Supp}\{\psi_{j,k}\} = [k2^{-j}, (k + 1)2^{-j}] = \bar{l}_{j,k}$$

The Haar coefficient on $\psi_{j,k}$ of a function $f$ is given by:

$$d_{j,k} = \int_{l_{j,k}} f \psi_{j,k}$$

If $f \in C^1(l_{j,k})$ then for all $x \in l_{j,k}$:

$$f(x) = f \left( x - \left( k + \frac{1}{2} \right) 2^{-j} \right) + \left( x - \left( k + \frac{1}{2} \right) 2^{-j} \right) f'(\theta_x), \quad \theta_x \in l_{j,k}$$

Then,

$$d_{j,k} = \int_{l_{j,k}} \left( x - \left( k + \frac{1}{2} \right) 2^{-j} \right) f'(\theta_x) \psi_{j,k}(x) \, dx$$

since $\int \psi_{j,k} = 0$, hence

$$|d_{j,k}| \leq \sup_{l_{j,k}} |f'| \int_{l_{j,k}} 2^{-j-1} 2^{j/2} \, dx \leq \frac{1}{2} \sup_{l_{j,k}} |f'| \, 2^{-3j/2}$$
Example: $f(x) = \sqrt{|\cos 2\pi x|}$

**Left figure:** function $f$ sampled on $1024 = 2^{10}$ values.

**Middle figure:** Haar coefficient map
(abscissa : $k2^{-j} \in [0, 1]$, ordinates: $-j$, $j = 1, \ldots 9$).

Multiresolution Analysis (MRA)

A multiresolution analysis of $L^2(\mathbb{R})$ is a sequence of closed subspaces $(V_j)_{j \in \mathbb{Z}}$ s.t.:

1. $\forall j \in \mathbb{Z}, \ V_j \subset V_{j+1} \subset \cdots \rightarrow L^2(\mathbb{R})$,
2. $\bigcap_{j \in \mathbb{Z}} V_j = \{0\}$ and $\bigcup_{j \in \mathbb{Z}} V_j = L^2(\mathbb{R})$,
3. $f(x) \in V_j \iff f(2x) \in V_{j+1}$,
4. $f(x) \in V_0 \iff \forall n \in \mathbb{Z}, \ f(x - n) \in V_0$,
5. $\exists \varphi \in V_0$ s.t. $\{\varphi(x - n) : n \in \mathbb{Z}\}$ is an orthonormal basis of $V_0$.

$\varphi$ is called the scaling function of the multiresolution analysis.
Multiresolution Analyses – Examples

The spaces $V_j$ are dilation invariant, then:

$$V_j = \text{Vec} \{ \varphi_{j,k} := 2^\frac{j}{2} \varphi(2^j x - k) \ ; \ k \in \mathbb{Z} \}$$

Haar:

$$V_0 = \{ \text{Piecewise constant functions on } [k, k+1[, \ \forall k \in \mathbb{Z} \}$$

Splines of degree 1:

$$V_0 = \{ \text{Continuous functions on } \mathbb{R}, \ \text{affines on } [k, k+1[, \ \forall k \in \mathbb{Z} \}$$

Splines of degree $n$:

$$V_0 = \{ C^{n-1} \text{ functions on } \mathbb{R}, \ \text{piecewise polynomial of deg } n \text{ on } [k, k+1[ \}$$

Shannon:

$$V_0 = \{ f \in L^2(\mathbb{R}) \ ; \ \text{supp } \hat{f} \subset [1, 2] \}$$
MRA – Two-scale equation for the scaling function

\[ V_0 \subset V_1 = \text{span}\{\phi_{1,k} := \sqrt{2}\phi(2x - n) ; n \in \mathbb{Z}\} \], then \( \phi \in V_0 \) writes:

\[ \phi(x) = \sqrt{2} \sum_{n \in \mathbb{Z}} h_n \phi(2x - n) \quad \text{with} \quad h_n = \sqrt{2} \int_{\mathbb{R}} \phi(x) \phi(2x - n) \, dx \]

Applying the Fourier Transform:

\[ \hat{\varphi}(\xi) = m_0 \left( \frac{\xi}{2} \right) \hat{\varphi} \left( \frac{\xi}{2} \right) \quad \text{with} \quad m_0(\xi) = \frac{1}{\sqrt{2}} \sum_{n \in \mathbb{Z}} h_n e^{-2i\pi n\xi} \]

Assume that \( \phi \in L^1(\mathbb{R}) \) and \( \int_{\mathbb{R}} \phi = 1 \), then:

\[ \hat{\varphi}(\xi) = \prod_{j=0}^{\infty} m_0 \left( \frac{\xi}{2^j} \right) \]

(\( h_n \)) is a low pass filter and \( m_0 \) is its transfer function.
MRA – Construction of the wavelets

$V_j \subset V_{j+1}$, let $W_j$ be the orthogonal complement space of $V_j$ in $V_{j+1}$:

$$V_{j+1} = V_j \oplus W_j$$

One searches for a function $\psi$ s.t. \{\psi(x - n) : n \in \mathbb{Z}\} is an orthonormal basis of $W_0$. Since $\psi \in W_0 \subset V_1$, one searches for $g_n$ such that

$$\psi(x) = \sqrt{2} \sum_{n \in \mathbb{Z}} g_n \varphi(2x - n)$$

This is equivalent in Fourier domain to:

$$\hat{\psi}(\xi) = m_1 \left( \frac{\xi}{2} \right) \hat{\varphi} \left( \frac{\xi}{2} \right) \quad \text{with} \quad m_1(\xi) = \frac{1}{\sqrt{2}} \sum_{n \in \mathbb{Z}} g_n e^{-2i\pi n \xi}$$

$\Rightarrow$ What are the assumptions on filters $(h_n)$ and $(g_n)$ in order to construct a scaling function $\varphi$ and a wavelet $\psi$ generating a MRA?
Detail filter (necessary) constraints for $h$

If $\{\varphi_{j,n}\}$ is an orthonormal basis of $V_j$ then:

1. From the two-scale equation it comes
   \[ \hat{h}(0) = \sqrt{2} \quad (C_1) \]

2. $\{\varphi(\cdot - n)\}_n$ orthogonal is equivalent to:
   \[ \forall n \in \mathbb{N}, \quad \varphi \ast \bar{\varphi}(n) = \delta[n] \iff \sum_k |\hat{\varphi}(\xi + 2k\pi)|^2 = 1 \]

since sampling a function periodizes its Fourier transform.

Inserting $\hat{\varphi}(\xi) = 2^{-1/2}\hat{h}(\xi/2)\hat{\varphi}(\xi/2)$ and separating even and odd integers terms (with $\hat{h}$ is $2\pi$-periodic) yields:

\[
\left| \hat{h}\left(\frac{\xi}{2}\right) \right|^2 \sum_{p=-\infty}^{+\infty} \left| \hat{\varphi}\left(\frac{\xi}{2} + 2p\pi\right) \right|^2 + \left| \hat{h}\left(\frac{\xi}{2} + \pi\right) \right|^2 \sum_{p=-\infty}^{+\infty} \left| \hat{\varphi}\left(\frac{\xi}{2} + \pi + 2p\pi\right) \right|^2 = 2
\]

Putting $\xi' = \xi/2$ and $\xi' = \xi/2 + \pi$ in the two sums yields:

\[ |\hat{h}(\xi')|^2 + |\hat{h}(\xi' + \pi)|^2 = 2 \quad (C_2) \]
Conversely, the following theorem gives sufficient conditions on $\hat{h}$ to guarantee that this infinite product is the Fourier transform of a scaling function:

**Theorem (Mallat, Meyer)**

If $\hat{h}(\xi)$ is $2\pi$-periodic and continuously differentiable in a neighborhood of $\xi = 0$, if it satisfies (C₁), (C₂) and

$$\inf_{\xi \in [-\pi/2, \pi/2]} |\hat{h}(\xi)| > 0 \quad (C₃)$$

then

$$\hat{\varphi}(\xi) = \prod_{p=1}^{+\infty} \frac{\hat{h}(2^{-p}\xi)}{\sqrt{2}}$$
Detail filter (necessary) constraints for $g$

$\Rightarrow$ If $\{\psi_{j,n}\}$ is an orthonormal basis of $W_j$ then:

1. $\{\psi(\cdot - n)\}_n$ orthogonal is equivalent to:

$$\forall n \in \mathbb{N}, \quad \psi \ast \psi(n) = \delta[n] \iff \sum_{k} |\hat{\psi}(\xi + 2k\pi)|^2 = 1$$

Inserting $\hat{\psi}(\xi) = 2^{-1/2} \hat{g}(\xi/2) \hat{\varphi}(\xi/2)$ and separating even and odd integers terms (with $\hat{g}$ $2\pi$-periodic) also yields:

$$|\hat{g}(\xi)|^2 + |\hat{g}(\xi + \pi)|^2 = 2 \quad (C_4)$$

2. $\{\psi(\cdot - n)\}_n$ orthogonal to $\{\varphi(\cdot - n)\}_n$ is equivalent to:

$$\forall n \in \mathbb{N}, \quad \psi \ast \varphi(n) = 0 \iff \sum_{k} \hat{\psi}(\xi + 2k\pi) \hat{\varphi}^*(\xi + 2k\pi) = 0$$

which leads to:

$$\hat{g}(\xi)\hat{h}(\xi)^* + \hat{g}(\xi + \pi)\hat{h}(\xi + \pi)^* = 0 \quad (C_5)$$
Detail filter (sufficient) constraints for $g$

Conversely, the following theorem gives sufficient conditions on $\hat{h}$ and $\hat{g}$ to guarantee that the constructed wavelets $\{\psi(\cdot - n)\}_n$ give an orthonormal basis of $W_j$:

Theorem (Mallat, Meyer)
Under conditions $(C_1) - (C_2) - (C_3)$

$$\{\psi(\cdot - n)\}_n \text{ orthonormal basis of } W_j \iff (C_4) + (C_5)$$

Quadrature mirror filters:

$$\hat{g}(\xi) = e^{-i2\pi\xi} \hat{h}(\xi + \pi) \iff g[n] = (-1)^{1-n} h[1 - n]$$
MRA – Wavelet decomposition

\[ L^2(\mathbb{R}) = V_0 \bigoplus_{j=0}^{+\infty} W_j = \bigoplus_{j=-\infty}^{+\infty} W_j \]

\[ W_j = \text{Vec} \{ \psi_{j,k}(x) = 2^{j/2} \psi(2^j x - k) ; \ k \in \mathbb{Z} \} \]

Let \( f \in L^2(\mathbb{R}) \). Its wavelet decomposition writes:

\[
\begin{align*}
f(x) &= \sum_{k \in \mathbb{Z}} c_k \varphi(x - k) + \sum_{j=0}^{+\infty} \sum_{k \in \mathbb{Z}} d_{j,k} \psi_{j,k}(x) \\
&= \sum_{j=-\infty}^{+\infty} \sum_{k \in \mathbb{Z}} d_{j,k} \psi_{j,k}(x)
\end{align*}
\]

with \( c_k = \langle f, \varphi(\cdot - k) \rangle \) and \( d_{j,k} = \langle f, \psi_{j,k} \rangle \).
Property of wavelet bases

- **Vanishing Moments.** A wavelet $\psi$ satisfies:

$$\int_{\mathbb{R}} \psi = 0$$

One usually impose $N$ Vanishing Moments:

$$\int_{\mathbb{R}} x^n \psi = 0, \ \forall n = 0, \ldots N - 1$$

- **Characterization of the local smoothness of $f$.** For $n \leq N$, $\alpha < N$
  (i) if $f \in C^n(V_{x_0})$ then $|d_{j,k}| \leq C 2^{-j(n+1/2)}$ (for $k2^{-j}$ "neighbor" of $x_0$)

(ii) if $f \in C^\alpha(x_0)$ i.e. $|f^{[\alpha]}(x) - f^{[\alpha]}(x_0)| \leq k|x - x_0|^{\alpha-[\alpha]}$ then

$$|d_{j,k}| \leq C 2^{-j(\alpha+1/2)} \quad \text{(for } k2^{-j} \text{ "neighbor" of } x_0)$$

$\Rightarrow$ Important property in view of compression
Examples of wavelets constructed from filters

Debauchies family

1. $\hat{h}(0) = \sqrt{2}$
2. $|\hat{h}(\xi)|^2 + |\hat{h}(\xi + \pi)|^2 = 2$
3. $p$ vanishing moments $\iff \forall k < p, \frac{d^k \hat{h}}{d \xi^k}(\pi) = 0$

$\Rightarrow$ orthogonal wavelets with minimal support $2p - 1$

- $p = 1$ (Haar): $h = [0.7071, 0.7071]$
- $p = 2$: $h = [0.4830, 0.8365, 0.2241, -0.1294]$
- $p = 3$: $h = [0, 0.3327, 0.8069, 0.4599, -0.1350, -0.0854, 0.0352]$

1st line: Meyer functions ($C^\infty$ and infinite number of vanishing moments).
2d line: Splines of degree 1 (2 vanishing moments).
Examples of scaling functions and wavelets

Scaling function (left) and wavelet (right) compactly supported:
1st line: D8 (4 vanishing moments).
2d line: Coifman C12 (4 vanishing moments).
Fast Wavelet transform (FWT)

Let \( f \) be a discrete 1D signal of length \( N = 2^J \).

**Step 0 of the algorithm:** computing the coefficients \( c_J = (c_{J,k}) \)

\[
c_{J,k} \approx 2^{-\frac{J}{2}} f(k2^{-J}), \quad k \in \mathbb{Z},
\]

(using \( \int \varphi = 1 \)). One consider the function \( f_J \) of \( V_J \):

\[
f_J = \sum_{k \in \mathbb{Z}} c_{J,k} \varphi_{Jk}
\]

**Decomposition:** \( V_J = V_0 \oplus W_0 \oplus \cdots \oplus W_{J-1} \)

For \( j = J, \ldots, 1 \) one uses \( V_j = V_{j-1} \oplus W_{j-1} \), and then \( \forall k \in \mathbb{Z} \):

\[
c_{j-1,k} = \sum_{n \in \mathbb{Z}} c_{j,n} h_{n-2k}
\]

\[
d_{j-1,k} = \sum_{n \in \mathbb{Z}} c_{j,n} g_{n-2k}
\]
Fast Wavelet transform (FWT)

Proof: From the two-scale equation

\[ \varphi(x) = \sqrt{2} \sum_{n \in \mathbb{Z}} h_n \varphi(2x - n) \]

by replacing \( x \leftarrow 2^j x - k \) and multiplying by \( 2^{j/2} \) we get:

\[
2^{j/2} \varphi(2^j x - k) = 2^{j/2} \sqrt{2} \sum_{n \in \mathbb{Z}} h_n \varphi(2^{j+1} x - (n + 2k))
\]

\[
\varphi_{j,k}(x) \overset{n \leftarrow n - 2k}{=} \sum_{n \in \mathbb{Z}} h_{n-2k} \varphi_{j+1,n}
\]

\[
\langle f, \cdot \rangle \overset{c_{j,k}}{=} \sum_{n \in \mathbb{Z}} h_{n-2k} c_{j+1,n}
\]

Example (Haar wavelets)

- Low-pass filter: \( h = [\cdots, 0, \frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}, 0, \cdots] \)
- High-pass filter: \( g = [\cdots, 0, \frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}, 0, \cdots] \)
Fast Wavelet transform (FWT)

Noting \( c_j = (c_j, k)_{k \in \mathbb{Z}} \): 

\[
\begin{align*}
\text{convolution - decimation:} \\
&c_{j-1}[k] = (c_j \ast \hat{h})[2k], \quad \forall k \in \mathbb{Z} \\
d_{j-1}[k] = (c_j \ast \hat{g})[2k], \quad \forall k \in \mathbb{Z}
\end{align*}
\]

with \( \hat{h}[n] = h[-n] \) and \( \hat{g}[n] = g[-n] \).

The 2D Discrete Wavelet Transform
The 2D Haar Basis

From $\varphi(x)$ and $\psi(x)$ one can define the bidimensional functions:

$$
\Phi(x, y) = \varphi(x)\varphi(y), \quad \Psi^1(x, y) = \psi(x)\varphi(y)
$$
$$
\Psi^2(x, y) = \varphi(x)\psi(y), \quad \Psi^3(x, y) = \psi(x)\psi(y)
$$

The values of $\Psi^1$, $\Psi^2$ and $\Psi^3$ on $[0, 1] \times [0, 1]$ are:

```
1 -1
1
-1
1
```

For $i = 1, 2, 3$, $j \geq 0$ et $k = (k_x, k_y)$, $0 \leq k_x, k_y \leq 2^j - 1$ :

$$
\Psi^i_{j,k}(x, y) = 2^{\frac{j}{2}} \Psi^i(2^j x - k_x, 2^j y - k_y)
$$

The family $\{\Phi, \Psi^1_{j,k}, \Psi^2_{j,k}, \Psi^3_{j,k}\}$ is an orthonormal basis of $L^2([0, 1]^2)$. 
2D Haar expansion

\[ f = C_0 + \sum_{j=0}^{+\infty} \sum_{k_x, k_y=0}^{2^j-1} \left( D_{j,k}^1 \psi_{j,k}^1 + D_{j,k}^2 \psi_{j,k}^2 + D_{j,k}^3 \psi_{j,k}^3 \right) \]

with \( C_0 = \int \int_{[0,1]^2} f \) and \( D_{j,k}^i = \int \int_{[0,1]^2} f \ \psi_{j,k}^i \)
Example: square

Original image and compressed images:

Middle figure: keeping the 1024 largest coefficients (compression 98.4%).

Right Figure: keeping the 3467 largest coefficients (compression 94.7%).
The wavelet bases 2D are constructed by tensor product of 1D bases. Let $\varphi$ and $\psi$ be the scaling function and wavelet of a MRA. Two constructions are available: 

(1) Pure tensor product wavelet bases (anisotropic): 

$$\psi_{j,j'}^{k,k'}(x, y) = \psi_j(x) \psi_{j'}(y), \quad j, j' \in \mathbb{Z}, k, k' \in \mathbb{Z}$$

The associated 2D wavelet transform uses 1D FWT on lines followed by 1D FWT on columns of the image.

(2) Wavelets arising from tensor product 2D MRA of $L^2(\mathbb{R}^2)$:

- **Approximation space** (scaling functions) $\mathcal{V}_j = \mathcal{V}_j \otimes \mathcal{V}_j$
- **Detail spaces** (wavelets) $\mathcal{W}_j$ defined by $\mathcal{V}_{j+1} = \mathcal{V}_j \oplus \mathcal{W}_j$

$$\mathcal{V}_{j+1} = \mathcal{V}_{j+1} \otimes \mathcal{V}_{j+1}$$

$$= (\mathcal{V}_j \oplus \mathcal{W}_j) \otimes (\mathcal{V}_j \oplus \mathcal{W}_j)$$

$$= (\mathcal{V}_j \otimes \mathcal{V}_j) \oplus (\mathcal{W}_j \otimes \mathcal{V}_j) \oplus (\mathcal{V}_j \otimes \mathcal{W}_j) \oplus (\mathcal{W}_j \otimes \mathcal{W}_j)$$

Take home message

Question: CWT (discretized) or DWT?

Answer: depends on the application

- **CWT** for feature detection (no *a priori* choice for $a$, $b$): more flexible, more robust to noise, but only *frames* in general.
- **DWT** for large amount of data, data compression: *bases*, faster, but more rigid (need generalization)

Generalizations

- Biorthogonal wavelets
- Wavelet packets
- Continuous wavelet packets (integrated wavelets)
- Redundant WT (on a rectangular lattice)
- Second generation wavelets (lifting scheme)
- ...
Linear and nonlinear approximations in wavelet bases
Linear approximation

- **Orthogonal projection over the space** $V_J$

$$P_J : L^2(\mathbb{R}) \rightarrow V_J$$

$$f \mapsto \sum_{k \in \mathbb{Z}} \langle f, \varphi_{J,k} \rangle \varphi_{J,k} = \sum_{j \leq J-1} \sum_{k \in \mathbb{Z}} \langle f, \psi_{j,k} \rangle \psi_{j,k}$$

- **Strang-Fix condition** of order $N$ ($x^n \in V_0$):

$$\forall n = 0, \ldots, N-1, \quad x^n = \sum_{k \in \mathbb{Z}} a^n_k \varphi(x - k)$$

i.e $\psi$ has $N$ vanishing moments.

- **Projection error**:

$$\| f - P_J f \|_{L^2}^2 = \sum_{j=J}^{+\infty} \sum_{k \in \mathbb{Z}} |\langle f, \psi_{j,k} \rangle|^2$$
Linear approximation

**Theorem**

If $f \in H^s(\mathbb{R})$ with $s \leq N$, with

$$\| f - P_J f \|_{L^2} \leq C \ 2^{-Js} \| f \|_{H^s}$$

(cf. finite elements with $h = 2^{-J}$) then the following Sobolev-norm equivalence holds:

$$\| f \|_{H^s}^2 \sim \sum_{j=-\infty}^{+\infty} \sum_{k \in \mathbb{Z}} 2^{2Js} |\langle f, \psi_j, k \rangle|^2$$

$$\sim \| P_0 f \|_{L^2} + \sum_{j=0}^{+\infty} \sum_{k \in \mathbb{Z}} 2^{2Js} |\langle f, \psi_j, k \rangle|^2$$
Nonlinear approximation

Let \( N \in \mathbb{N} \). Let \( u \in L^2(\mathbb{R}) \), and its wavelet decomposition:

\[
u = u_0 + \sum_{j=0}^{+\infty} \sum_{k=-\infty}^{+\infty} d_{j,k} \psi_{j,k}\]

One sorts the wavelet coefficients \( d_{j,k} \) in decreasing order:

\[|d_{j_1,k_1}| > |d_{j_2,k_2}| > \cdots > |d_{j_{N-1},k_{N-1}}| > \cdots\]

and one introduces the best \( N \)-terms non-linear approximation

\[
\Sigma_N(u) = u_0 + \sum_{i=1}^{N} d_{j_i,k_i} \psi_{j_i,k_i}
\]

If \( u \in B_{q}^{s,q} \) with \( \frac{1}{q} = \frac{1}{2} + s \), which is equivalent to:

\[
\|u\|_{B_{q}^{s,q}}^q \sim \sum_{j \in \mathbb{Z}} \sum_{k \in \mathbb{Z}} |d_{j,k}|^q < +\infty
\]
Nonlinear approximation

The non-linear approximation error is defined as:

$$\| u - \Sigma_N(u) \|_{L^2}^2 = \sum \left| d_{j_i,k_i} \right|^2$$

Theorem

$$\| u - \Sigma_N(u) \|_{L^2} \leq C \left( \frac{1}{N} \right)^s \| u \|_{B^{s,q}}$$

(in dimension $d$, $s$ should be replaced by $s/d$).

Proof:

$$n \left| d_{j_n,k_n} \right|^q \leq \sum_{i=0}^{n-1} \left| d_{j_i,k_i} \right|^q \leq \sum_{i=0}^{+\infty} \left| d_{j_i,k_i} \right|^q = \sum_{j \in \mathbb{Z}} \sum_{k \in \mathbb{Z}} \left| d_{j,k} \right|^q \leq C \| u \|_{B^{s,q}}^q$$

Then

$$\left| d_{j_n,k_n} \right| \leq C n^{-1/q} \| u \|_{B^{s,q}}$$

$$\| u - \Sigma_N(u) \|_{L^2} \leq C \| u \|_{B^{s,q}} \left( \sum_{n \geq N+1} n^{-2/q} \right)^{1/2} \leq C N^{1/q} - \frac{1}{q} \| u \|_{B^{s,q}} = C N^{-s} \| u \|_{B^{s,q}}$$
Nonlinear approximation

Remarks

- For $N = 2^J$ one obtains the same convergence rate for the linear and nonlinear approximation. But $B^{s,q}_q$ is a space which contains more functions than the space $H^s$, for instance discontinuous functions for arbitrary large values of $s$, whenever functions of $H^s$ are necessarily continuous if $s > d/2$ ($d$ space dimension).
- One has also the characterization: if $u \in B^{s,q}_q$

\[
\text{Card} \left\{ \lambda : |d_\lambda| \geq \varepsilon \right\} \leq C\varepsilon^{-q}
\]
Compression factor of a turbulent 2D vorticity field

Figure: Analysis of a 2D turbulent field: vorticity field, its wavelet coefficients, and nonlinear approximation error, in terms of the number of retained coefficients
Denoising in orthonormal wavelet bases

References: articles of Donoho and Johnstone

Noised data:

\[ X[n] = f[n] + W[n], \quad n = 0, \ldots, N - 1 \]

- **X**: measured data
- **f**: (unknown) signal of size \( N \), corrupted by noise
- **W**: Gaussian white noise, with zero mean and variance \( \sigma^2 \)

The aim is to provide an estimator \( \tilde{F} = D(X) \) of \( f \) minimizing the risk (mean square error):

\[ r(D, f) = \mathbb{E} \left\{ \| f - \tilde{F} \|^2 \right\} = \sum_{n=0}^{N-1} \mathbb{E} \left\{ |f[n] - \tilde{F}[n]|^2 \right\} \]
Nonlinear estimators in bases

Let \( B = \{ g_k \in \mathbb{R}^N, k = 0, \ldots, N - 1 \} \) be an orthonormal basis of \( \mathbb{R}^N \).

One decomposes the noisy signal in \( B \):

\[
X[n] = \sum_{k=0}^{N-1} \langle X, g_k \rangle g_k [n]
\]

and the inner products satisfy:

\[
\langle X, g_k \rangle = \langle f, g_k \rangle + \langle W, g_k \rangle
\]

Remarks

- \( \langle W, g_k \rangle \) are independent Gaussian variables of variance \( \sigma^2 \) (since \( B \) is orthonormal).

- \( \mathbb{E} \{ \langle X, g_k \rangle \} = |\langle f, g_k \rangle|^2 + \sigma^2 \)
Diagonal operators

A diagonal operator $\mathcal{D}$ in the basis $\mathcal{B}$ leads to an estimator of the form:

$$\tilde{F} = \mathcal{D}X = \sum_{k=0}^{N-1} d_k (\langle X, g_k \rangle) g_k$$

where the $d_k$ are attenuation functions of the noisy coefficients.

**Ideal estimator** (i.e. which minimizes the risk $r(\mathcal{D}, f)$)

$$\tilde{F} = \mathcal{D}X = \sum_{k=0}^{N-1} \langle X, g_k \rangle \theta(k) g_k$$

with

$$\theta(k) = \begin{cases} 1 & \text{if } |\langle f, g_k \rangle| \geq \sigma \\ 0 & \text{if } |\langle f, g_k \rangle| < \sigma \end{cases}$$

In this case, the operator $\mathcal{D}$ is nonlinear.
Thresholding estimators

A thresholding estimator in the basis $\mathcal{B}$ corresponds to a *diagonal operator* $\mathcal{D}$:

$$F = \mathcal{D}X = \sum_{k=0}^{N-1} d_k (\langle X, g_k \rangle) g_k$$

where the $d_k$ are thresholding functions (let $T$ be a threshold):

$$d_k(x) = \rho_T(x) = \begin{cases} x & \text{if } |x| > T \\ 0 & \text{if } |x| \leq T \end{cases} \quad \text{("hard" thresholding)}$$

or

$$d_k(x) = \rho_T(x) = \begin{cases} x - T & \text{if } x \geq T \\ x + T & \text{if } x \leq -T \\ 0 & \text{if } |x| \leq T \end{cases} \quad \text{("soft" thresholding)}$$

- **Question**: choice of $T$ to approach the risk of the ideal estimator?
- **Answer**: the choice $T = \sigma \sqrt{2 \log_e N}$ leads to a risk slightly larger (Theorem of Donoho-Jonstone).
Wavelet thresholding

Consider a (periodic) wavelet basis:

\[ B = \{ \varphi, \psi_{j,k} \mid 0 \leq j \leq J-1, \; k = 0 : 2^j - 1 \} \; (N = 2^J = \text{size of the data}) \]

The thresholding estimator writes:

\[ \tilde{F} = \rho_T(\langle X, \varphi \rangle) \varphi + \sum_{j=0}^{J-1} \sum_{k=0}^{2^j-1} \rho_T \left( \langle X, \psi_{j,k} \rangle \right) \psi_{j,k} \]

**Estimation of the noise variance \( \sigma^2 \):**

If \( f \) is piecewise regular, a robust estimator is given by the median of the wavelet coefficients at the finest scale:

- \( \{ \langle X, \psi_{j,k} \rangle \}_{k=0:2^j-1} \; : \; 2^J - 1 = \frac{N}{2} \) wavelet coefficients of the noisy data at the finest scale.
- If \( \langle f, \psi_{j,k} \rangle \) is small (\( f \) is regular on the support of \( \psi_{J-1,k} \)), one has:
  \[ \langle X, \psi_{j,k} \rangle \approx \langle W, \psi_{j,k} \rangle. \]
Wavelet thresholding

- If $\langle f, \psi_{j,k} \rangle$ is large, it corresponds to a singularity of $f$, but for a piecewise regular functions with isolated singularity, only few coefficients $\langle X, \psi_{j,k} \rangle$ are affected at the finest scale.
- Then $\langle X, \psi_{j,k} \rangle$ is a random variable of variance $\sigma^2$.

The noise standard deviation $\sigma$ is estimated by the formula (exact for $P = 2^{J-1}$ independent Gaussian variables, of zero mean, and variance $\sigma^2$):

$$\sigma \approx \frac{M_X}{0.6745}$$

where $M_X$ is the median of the coefficients $\{\langle X, \psi_{j,k} \rangle\}_{k=0:2^{J-1}-1}$ at the smallest scale.

Example:

$$f(x) = \sqrt{|\cos 2\pi x|} + \text{noise (discretized on } 1024 = 2^{10} \text{ values)}$$
Example: \( f(x) = \sqrt{|\cos 2\pi x|} + \text{noise} \)
Example: \( f(x) = \sqrt{|\cos 2\pi x|} + \text{noise} \)
Example: Piece-Regular
Example: WaveLab denoising function

%Generation of a signal y
n=1024; dx=1/n; x=(0:n-1)/n;
alpha=0.1 % noise coefficient
y=sqrt(abs(cos(2*pi*x)));

or

y=MakeSignal('Piece-Regular',n);

% y=y+alpha*randn(size(y)); % add Gaussian noise
plot(x,y) % plot of the noisy signal

% Denoising by hardtresholding on orthonormal wavelet coeff 'Symmlet 4'
out=ThreshWave(y);
plot(x,out) % plot the denoised signal
Sparse representation and approximation
Analysis vs. synthesis

- **Analysis**: \( \Phi(f) = \{ \langle f, \phi_p \rangle \}_{p \in \Gamma} \)
- **Synthesis**: \( f = \sum_p \langle f, \phi_p \rangle \phi_p \)

Suppose that a sparse family of vectors \( \{ \phi_p \}_{p \in \Lambda} \) has been selected to approximate a signal \( f \). An **approximation** can be recovered as an orthogonal projection in the space \( V_\Lambda \) generated by these vectors.

1. In a **dual-synthesis** problem, the orthogonal projection \( f_\Lambda \) of \( f \) in \( V_\Lambda \) is computed as above from the inner products \( \{ \langle f, \phi_p \rangle \} \) provided by an analysis operator, whose only a subset of such inner products is selected and possibly thresholded.

2. In a **dual-analysis** problem, the decomposition coefficients of \( f_\Lambda \) must be computed on a family of selected vectors \( \{ \phi_p \}_{p \in \Lambda} \), by pursuit algorithms which compute approximation supports in highly redundant dictionaries.
Sparse representation and approximation
Approximation in bases vs. redundant dictionaries

1. Choose an **orthogonal basis** \( B = \{ \phi_p \}_{p \in \Gamma} \) for which the representation is **not redundant** at all, so we get a representation which is **sparse** and **stable**
   - By selecting the first \( M \) coefficients (**linear approximation**)
   - By selecting the \( M \) largest coefficients (**non-linear approximation**)

The size support \( M = |\Lambda| \) of \( f_M \equiv f_\Lambda \) needed to have a good approximation error \( \| f - f_M \| \) depends on the **regularity** of \( f \).

2. Choose a **dictionary** \( D = \{ \phi_p \}_{p \in \Gamma} \) which is **highly redundant** in order to obtain a **more sparse** representation (e.g. natural languages use redundant dictionaries). Identifying **patterns** or **features** consist on finding which vectors (**atoms**, words, ...) to choose to approximate

\[
  f \approx f_\Lambda = \sum_{p \in \Lambda} \alpha_p \phi_p
\]

Famous algorithms: Matching pursuit, Orthogonal Matching Pursuit (OMP), Basis pursuit, ...
Sparse representation and approximation
Moving from transforms to dictionaries

- "Xlets" (curvelets, bandlets, contourlets, ...) take advantage of the image geometric regularity
- Redundant dictionaries can improve approximation, compression and denoising
- Optimal approximation finding is NP-hard, only approximated with matching or basis pursuits
- Great impact to inverse problems
  - Compressed sensing
  - Super-resolution
  - Source separation
- Can be used for pattern recognition but problems of instabilities
- Deep learning made a breakthrough in classification and pattern recognition (dictionaries are learned i.e. linear operators/filters, but need a lot of examples). Increase the level of adaptability.

⇒ have wavelets become *has-been*?
The Scattering Transform
Understanding deep convolutional networks

Supervised learning against high dimension

- Data in high dimension $x \in \mathbb{R}^d$ with $d \approx 10^6$
- $f(x)$ represents a label of a class (whose can be also big, e.g $2 \cdot 10^3$ for ImageNet) for classification tasks, or a real for regression.
- Training set of $n$ samples $\{x_i, y_i = f(x_i)\}_{i \leq n}$ (few samples per class)
- Supervised learning aims at generalizing from the samples to predict $f(x)$ for new datas.

Intuitively, to do an interpolation in $x$ we need somehow to average among known samples $\{x_i, y_i\}$ in the neighborhood of $x$, saying:

$$\forall x \in [0, 1]^d, \exists x_i \in [0, 1]^d, \quad \|x - x_i\| \leq \epsilon$$

then if the $x_i$’s are uniformly distributed, it would require $\epsilon^{-d}$ points to cover $[0, 1]^d$ entirely!

Points are far away in high dimension $\Rightarrow$ Curse of dimensionality
Understanding deep convolutional networks

Kernel learning

1. **Representation.** Change of variable \( \Phi(x) = \{\phi_k(x)\}_{k \leq d'} \) (features) in order to nearly linearize class boundaries:

\[
x = (v_1, \ldots, v_d) \underset{\Phi}{\rightarrow} \Phi(x) = (v'_1, \ldots, v'_d)
\]

2. **Classifier.** Find an hyperplan (that is an vector \( w \) orthogonal to the hyperplan) which separates the transformed data:

\[
\tilde{f}(x) = \text{sign}(\langle \Phi(x), w \rangle + b) = \text{sign}\left(\sum_k w_k v'_k + b\right)
\]

Questions:
- How to construct such a representation \( \Phi \)?
- What regularity is needed?
- Can wavelets be useful to understand and draw CNN architectures?

Understanding deep convolutional networks

The "3S" ingredients for reducing the dimensionality problem

1. **Separability**: variables separation can reduce the dimensionality from \( d \) to \( K \) problems of dimension \( q \ll d \) (e.g decomposing an image \( 10^3 \times 10^3 \) in small independant patches \( 8 \times 8 \), whose interactions between pixels are essentially local \( \Rightarrow \) SIFT). It is important to make **scales separation** but also to capture their interaction: deeper neurons can "see" greater portion of the image.

2. **Symmetry**: spatial symmetries produce **translation/rotation/flip invariance** (e.g convolution filters induce translation invariance) and reduce the dimensionality by eliminating some variables.

3. **Sparsity**: pattern recognition consists on decomposing the problem on sparse **elementary structures** in dictionaries (cat’s hears, human’s eyes, ...) in particular through the activation functions.

\( \Rightarrow \) take advantage both of *a priori* information hard-coded in the network architecture and learning to design \( \Phi \).
Symmetry group

To know the regularity of \( f \) one can study it through local but also global transformation such that symmetry group of \( f \):

\[
G = \{ g : \forall x \in \Omega, \quad f(g.x) = f(x) \}
\]

- The functions \( g \) preserve the level sets \( \Omega_t = \{ x : f(x) = t \} \), that is if \( x \in \Omega_t \) and \( g \in G \) then \( g.x \in \Omega_t \). So it is easy to verify the solutions of a level set has a structure of group.

- **Information a priori**, a symmetry subgroup \( H \subset G \). If \( g \in H \) then \( x \) and \( g.x \) have the same label \( f(g.x) = f(x) \), so belong to the same class of equivalence. The quotient of \( \Omega \) by \( H \) is denoted by \( \Omega \backslash H \), for \( x_0 \in \Omega \backslash H \) then it defines a class of equivalence:

\[
H_{x_0} = \{ x \in \Omega : g \in H \text{ s.t } g.x = x_0 \}
\]

**Example**: if \( x_0 \) is an image and \( f(x_0) \) its label (cat/dog), then by translating \( x = g.x_0 \in H_{x_0} \) the label remains the same \( f(x) = f(x_0) \).

- One can then reduce the number of variables (variability) within the class of equivalence (reduction of dimensionality).
Symmetry group
Lie group: infinitely small generators

Reduction of dimensionality in the continuous case:
\[ \dim(\Omega \setminus H) = \dim(\Omega) - \dim(H) \]

Diffeomorphisms group

Let \( g : [0, 1]^2 \to [0, 1]^2 \) be a \( C^1 \) function acting on the underlying variable of \( x \), namely \( u \) which is a low-dimensionnal quantity:
\[ g.(x(u)) = x(g(u)) \]

Examples
- Translation: \( g.x(u) = x(u - g) \) with \( g \in \mathbb{R}^2 \)
- Rotation: \( g.x(u) = x(R_g u) \) with \( g \in [0, 2\pi] \)
- Globally invariant to the translation group \( \Rightarrow \) small
- Locally invariant to small diffeomorphisms \( \Rightarrow \) HUGE

Continuous transports by successive action of generators \( f(x_i) = f(x_0) \)
\[ O_x = \{ g.x \}_{g \in G} \] (orbit = differentiable surface of iso-label)
Understanding deep convolutional networks

Using the information \emph{a priori} on the symmetry group of $f$ to define the representation $\Phi$ for the final classification/regression (last layer):

$$\tilde{f}(x) = \langle \Phi(x), w \rangle = \sum_{k} w_k \phi_k$$

In order that $\tilde{f}$ is a good approximation of $f$, we impose that it has the same invariants $g \in G$ that is $G$ is a symmetry group of $\Phi$.

Two possibilities:

1. \textbf{$G$ known and low dimension} (translation, rotation, ...)
   \Rightarrow \text{constructing directly } \Phi

2. \textbf{$G$ unknown and high dimension} (diffeomorphisms)
   \Rightarrow \text{linearization} + \text{learning} invariant through the classifier.

$$\tilde{f}(x) = \tilde{f}(g.x) \Rightarrow \langle \Phi(x), w \rangle = \langle \Phi(g.x), w \rangle \Rightarrow \langle \Phi(x) - \Phi(g.x), w \rangle = 0$$

$$\Phi(x) - \Phi(g.x) \in V \perp w$$

\Rightarrow If \ $V$ \ is a hyperplan it implies to linearize transformations, by considering small deformations $g$. 

Kévin Polisano
Wavelets and Applications
273/291
Linearization of small deformations

- **Linearize group actions**: \( g \cdot x = x + \tau . x \) so locally the tangent hyperplane to the orbit \( O_x \) is given by \( \tau \) (Lie algebra).

- **For small deformations** \( g \cdot x (u) = x (u - \tau (u)) \) we can write the action \( \tau \) as a "global" action (the translation) and a small "local" action (the deformation), since \( \tau (u) \approx \tau (u_0) + \nabla \tau (u_0) (u - u_0) \) then

\[
x (u - \tau (u)) = x (\underbrace{\mathbb{I} - \nabla \tau (u_0)}_{\text{local deformation}}) (u - u_0) + \underbrace{u_0 - \tau (u_0)}_{\text{global translation}}
\]

- **Distance** for small deformations: \( |g|_G = \| \tau \|_\infty + \| \nabla \tau \|_\infty \)

- We do not know in advance what is the local range of diffeomorphism symmetries.

**Example**: to classify images \( x \) of handwritten digits, certain deformations of \( x \) will preserve a digit class but modify the class of another digit.
Linearization of small deformations

• We shall linearize small diffeomorphims $g$ via the change of variable $\Phi(x)$, which is say Lipschitz-continuous if

$$\exists C > 0, \forall (x, g) \in \Omega \times G, \quad \|\Phi(g.x) - \Phi(x)\| \leq C \|g\|_G \|x\|$$

• The Radon–Nikodim property proves that the map that transforms $g$ into $\Phi(g.x)$ is almost everywhere differentiable in the sense of Gâteaux. If $|g|_G$ is small, then $\Phi(g.x) - \Phi(x)$ is closely approximated by a bounded linear operator of $g$, which is the Gâteaux derivative. **Locally, it thus nearly remains in a linear space.**

⇒ The Lipschitz property of $\Phi$ is difficult to be obtained. Indeed, a local deformation is a dilation, so the representation will have to be based on dilations, that is we will need to separate scales with the wavelet transform.
Stable invariants

Fourier is not relevant

If $\Phi(x) = \{|\hat{x}(\omega)|\}_\omega$ then:

- **Invariance to translations** $x_c(t) = x(t - c)$

  $$\forall c \in \mathbb{R}, \quad \Phi(x_c) = \Phi(x)$$

- **Not Lipschitz stable to small deformation** $x_\tau(t) = x(t - \tau(t))$ where $\tau(t) = \epsilon t$ for example. The Fourier transform of $x(t - \tau(t)) = x((1 - \epsilon)t)$ is $\hat{x}(\omega(1 + \epsilon))$, so two "bumps" centered in $\omega = \pm \omega_0$ will be "shifted" toward low frequencies by a quantity $\epsilon \omega_0$, such that they are not superposed anymore and then

  $$\|\Phi(x_\tau) - \Phi(x)\| \neq \epsilon$$

$\Rightarrow$ Wavelets are localized waveforms and are thus stable to deformations, as opposed to Fourier sinusoidal waves
Stable invariants

Why wavelets?

- Wavelets are uniformly stable to deformations:
  If $\psi_{\lambda,\tau}(t) = \psi_\lambda(t - \tau(t))$ then

\[ \|\psi_\lambda - \psi_{\lambda,\tau}\| \leq C \sup_t |\nabla \tau(t)| \]

- Wavelet separate multiscale information
- Wavelets provide sparse representation
Multiscale Wavelet Transform

- Complex wavelet $\psi(u) = \psi^a(u) + i\psi^b(u)$
- Dilated 1D wavelet: $\psi_\lambda(u) = 2^{-j/Q}\psi(2^{-j/Q}u)$ with $\lambda = 2^{-j/Q}$
- For images with two variables $u = (u_1, u_2)$ add a rotation $r \in G$ of angles $2k\pi/K$ for $0 \leq k < K$:
  $$\psi_\lambda(u) = 2^{-2j}\psi(2^{-j}r^{-1}u), \quad \lambda = (2^{-j}, r)$$
- Wavelet transform:
  $$Wx = \begin{pmatrix}
x \ast \phi(u) \\
x \ast \psi_\lambda(u)
\end{pmatrix}_{u,\lambda}$$
- If $|\hat{\phi}(\omega)|^2 + \sum_\lambda |\hat{\psi}_\lambda(\omega)|^2 = 1$ then $W$ is unitary: $\|Wx\|^2 = \|x\|^2$
Stable translation invariance

- $x \star \psi_\lambda$ is translation covariant, not invariant and

$$\int x \star \psi_\lambda(u) \, du = 0$$

- Translation invariant representation: $\int M(x \star \psi_\lambda)(u) \, du$
- Diffeomorphism stability: $M$ commutes with diffeomorphisms
- $L^2$ stability: $\|Mh\| = \|h\|$ and $\|Mg - Mh\| \leq \|g - h\|

$$\Rightarrow M(h)(u) = |h(u)| = \sqrt{|h^a(u)|^2 + |h^b(u)|^2}$$
Wavelet translation invariance

- The modulus $|x \ast \psi_{\lambda_1}| = \sqrt{|x \ast \psi^{a}_{\lambda_1}|^2 + |x \ast \psi^{b}_{\lambda_1}|^2}$ (pooling) is a regular envelop.
- The average $|x \ast \psi_{\lambda_1}| \ast \phi(t)$ is invariant to small translations relatively to the support of $\phi$.
- Full translation invariance at the limit:
  $$\lim_{\phi \to 1} |x \ast \psi_{\lambda_1}| = \int |x \ast \psi_{\lambda_1}(u)| \, du = \|x \ast \psi_{\lambda_1}\|_1$$
- First Wavelet transform modulus:
  $$\rho W_1 = |W_1| x = \left( \begin{array}{c} x \ast \phi_{2J} \\ |x \ast \psi_{\lambda_1}| \end{array} \right)_{\lambda_1}$$
- Second Wavelet transform modulus (for recovering high freq. lost):
  $$|W_2||x \ast \psi_{\lambda_1}| = \left( \begin{array}{c} |x \ast \psi_{\lambda_1}| \ast \phi_{2J} \\ ||x \ast \psi_{\lambda_1}| \ast \psi_{\lambda_2}| \end{array} \right)_{\lambda_2}$$
- Translation invariance by averaging $||x \ast \psi_{\lambda_1}| \ast \psi_{\lambda_2}| \ast \phi_{2J}$, $\forall \lambda_1, \lambda_2$.
Scattering Network

Scattering Properties

\[
S_J x = \begin{pmatrix}
x_2^J \\
|x_1^J \star \phi_2^J| \\
|x_1^J \star \phi_2^J| \\
|x_1^J \star \phi_2^J| \\
\vdots
\end{pmatrix} = \cdots \left| W_3 \right| \left| W_2 \right| \left| W_1 \right| x
\]

Lemma: \( \left| W_k D_\tau - D_\tau W - k \right| \leq C \left\| \nabla \tau \right\|_\infty \) where \( D_\tau x(u) = x(u - \tau(u)) \)

Theorem (Mallat et al.)

For appropriate wavelets, a scattering is contractive

\[
\left\| S_J x - S_J y \right\| \leq \left\| x - y \right\|
\]

translations invariance and deformation stability:

\[
\lim_{J \to +\infty} \left\| S_J D_\tau x - S_J x \right\| \leq C \left\| \nabla \tau \right\|_\infty \left\| x \right\|
\]

Fig. 2. A scattering propagator \( \mathcal{W} \) applied to \( x \) computes the first layer of wavelet coefficients modulus \( U[\lambda_1]x = |x \ast \psi_{\lambda_1}| \) and outputs its local average \( S[\emptyset]x = x \ast \phi_{2^j} \) (black arrow). Applying \( \mathcal{W} \) to the first layer signals \( U[\lambda_1]x \) outputs first order scattering coefficients \( S[\lambda_1] = U[\lambda_1] \ast \phi_{2^j} \) (black arrows) and computes the propagated signal \( U[\lambda_1, \lambda_2]x \) of the second layer. Applying \( \mathcal{W} \) to each propagated signal \( U[p]x \) outputs \( S[p]x = U[p]x \ast \phi_{2^j} \) (black arrows) and computes a next layer of propagated signals.
Understanding deep convolutional networks

Simplified architecture: Deep Convolutional Trees

Architecture

- Convolutional filters $L_j$: band-limited wavelets
- Pooling: $L^1$ norm as averaging
- Nonlinear activation $\rho$: modulus

$\Phi(x) = S_J x$ (scattering vector)

Credits: S. Mallat
Experiments and results

MNIST dataset for **digit classification**: for a training of 50,000 digits the classification error of the Scattering Network was similar to the Convolutional Network’s (0.4 %)
Experiments and results

- CUReT dataset for **textures classification**: for a small training set of textures $200 \times 200$ in 61 classes (46 per class), the classification error with the Scattering Network achieves 0.2 %, far better than Fourier transform’s one (1 %)
Experiments and results

Scattering coefficients

Fig. 3. To display scattering coefficients, the disk covering the image frequency support is partitioned into sectors \( \Omega[p] \), which depend upon the path \( p \). (a): For \( m = 1 \), each \( \Omega[\lambda_1] \) is a sector rotated by \( r_1 \) which approximates the frequency support of \( \hat{\psi}_{\lambda_1} \). (b): For \( m = 2 \), all \( \Omega[\lambda_1, \lambda_2] \) are obtained by subdividing each \( \Omega[\lambda_1] \).

Fig. 4. (a) Two images \( x(u) \). (b) Fourier modulus \( |\hat{x}(\omega)| \). (c) First order scattering coefficients \( Sx[\lambda_1] \) displayed over the frequency sectors of Figure 3(a). They are the same for both images. (d) Second order scattering coefficients \( Sx[\lambda_1, \lambda_2] \) over the frequency sectors of Figure 3(b). They are different for each image.
Experiments and results

Scattering coefficients

Fig. 7. (a): Image $X(u)$ of a digit '3'. (b): Arrays of windowed scattering coefficients $S[p]X(u)$ of order $m = 1$, with $u$ sampled at intervals of $2^J = 8$ pixels. (c): Windowed scattering coefficients $S[p]X(u)$ of order $m = 2$.

Figure 4.3: (a): Example of CureT texture $X(u)$. (b): Scattering coefficients $S_J[p]X$, for $m = 1$ and $2^J$ equal to the image width. (c): Scattering coefficients $S_J[p]X(u)$, for $m = 2$. 
Fig. 5. (a) Realizations of two stationary processes $X(u)$. Top: Brodatz texture. Bottom: Gaussian process. (b) The power spectrum estimated from each realization is nearly the same. (c) First order scattering coefficients $S[p]X$ are nearly the same, for $2^J$ equal to the image width. (d) Second order scattering coefficients $S'[p]X$ are clearly different.
Take home message

Interpretation of convolutional networks

- Deep convolutional network are really efficient to approximate functions in very high dimension
- Compute multiscale invariants of complex symmetries and learn sparse patterns
- Many mathematical questions still open (notion of regularity, complexity, approximation theorems, ...)
